# THE EFFECT OF ILLICIT TRADE IN NARCOTICS ON GLOBAL ECONOMY

**Alasmari Khaled**

*Department of International Business and Economics, ASE, Bucharest .*

**email address: haql@hotmail.com**

**Abstract:** *Illicit markets especially those dealing with narcotics constitute grievous issues to the world's economies, putting to test global safety, economic progress as well as security and many other aspects. Seemingly, illicit narcotics trade in the last decade – that is 2000 to 2011 underwent a significant boom, resulting from a wide spectrum of illegal drugs such as cocaine as well as heroin among many other hard drugs. In today's global society, several concerns are emerging on the rise of illicit narcotics trade accompanied with organized crime, chiefly as major hindrances to consistent global economic progress. Apparently, some of the effects of illicit narcotics trade are that; this trade gradually turns upside down business rules, opening way for new unruly market players besides reconfiguring influence in global economics as well as politics. Surprisingly, the revenue from illegal drugs in 2011 alone was roughly 10% of the global GDP. Hence, exaggerating local economies' incomes and triggering ceaseless conflicts among market players, while at the same time reducing legal business activities likewise disintegrating socioeconomic conditions. An empirical research method was adopted for this study, analyzing illicit trade in narcotics on the global arena as from 2000 to 2011 and its resultant effects. The research findings indicate that, illegal drugs trade particularly on the world economy besides growing at a high rate, it endangers the overall welfare of humans likewise the business environment. This is ostensibly because this trade has high chances of engrossing regional economies into illegal drugs business activities, causing them to neglect sustainable ethical businesses. Now, to effectively address negative economic issues related to illegal drugs trade, there is apparent need for integrated efforts from local as well as international authorities. Such efforts are chiefly to control not only the harmful effects resulting from the use of illicit narcotics, but also from the trade itself and to build sustainable economies. The findings of this study are crucial for regulatory authorities in the global economy, for them to adequately comprehend the effects of illicit trade in narcotics hence inform their decisions to take necessary measures. This paper is on the effect of illicit trade in narcotics on global economy, touching on issues like peace along with social cohesion as well as security and economic progress.*

## **Effect of illicit narcotics trade on global economy**

Illicit narcotics trade as discussed in (Birdsall, 2008: 163-167) is a worldwide illegal market sector that is also described as a black market undertaking. This illegal market chiefly focuses on cultivation along with processing as well as dispersion and sale of medicinal substances that are largely abused by human beings. Further,

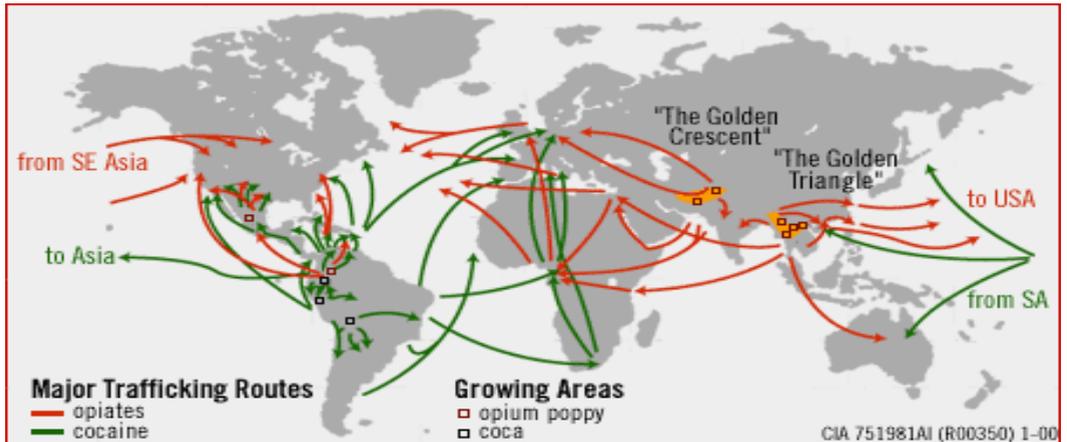

(Ellis, 2009: 171-196) indicates that a number of legal authorities worldwide continue to place strict measures that forbid business transactions for such substances, specifically for prohibited uses. However, their trade is only allowed where valid licenses are obtained from the recognized authorities. Notably, even with issuance of such licenses, it is argued in (Birdsall, 2008: 163-167) that still illicit narcotics trade continue to have far-reaching effects, on top of being a compromising market sector that either directly or indirectly alters the global economy's economic framework. This paper analyses the effects of illicit trade in narcotics, chiefly to establish its impact on the global economy. The research plan involves the analysis of empirical data on the research topic, specifically as from 2000 to 2011.

The history of illegal narcotics began as earlier as during the 19<sup>th</sup> century, with opium being the main as well as popular substance of discussion then. At that time, opium was widely traded among the British as well as Chinese merchants among other traders, enabling them make lucrative returns. In those times, this business' resultant effects included a rise in addiction cases among the Chinese people. As for the British merchants and the other traders, they got quick access to huge chunks of money from China, mainly as a form of compensation (Storti and Grauwe, 2011: 23-45). In the 21<sup>st</sup> century, since illegal drugs trade cause injection into different world economies secretive amounts of money that in turn is used to execute undesirable acts such as terrorism and even wars among others continues to receive criticisms. Also, with changes of time, more drugs such as heroin accompanied with cocaine among many others have made to the list of illicit narcotics trade (Jenner, 2011: 901-927).

**On average**, the global economy as discussed in (Ellis, 2009: 26-35) has developed at a faster rate, where these developments are from a range of factors such as expansion of upcoming economies inclusive of India, Eastern Europe along with China among many other upcoming economies. It has also emerged that, with development of the world economy is the widespread of social ills, the likes of illicit narcotics transactions that have widely penetrated in the international market scene. For instance, ***in the recent past as discussed in*** (Jenner, 2011: 901-927), ***there has been massive rise in illicit drugs trade for example of cocaine along with heroin among many others, characterised by extensive drugs networks together with dangerous criminal groups. Today, as illicit narcotics trade continues to gain ground in world economies, the major worrying issues are that the extent as well as geographical coverage of such illegal activities has no precedent. Also, the other alarming issue touches on unaccounted for income, where for instance in 2009 alone the overall amount of money got from trade in illegal narcotics was roughly US \$ 1.25 Trillion that up to now is yet to be accounted for*** (Hubschle, 2011: 25-40).

Moreover, Illicit narcotics trade as discussed in (Hubschle, 2011, p.25-40) is not a new subject not only within domestic economies but also in the global arena.

**Moreover, the** (UNODCCP, 1999: 51-55) indicates that illicit drugs trade derives its shape courtesy of numerous factors including historical aspects, location and population as well as reigning economic circumstances, hence few countries are least affected by this trade. Therefore, illicit drugs trade unavoidably stretches into every aspect of the global society. The figure below is an indicator of the Drug connections on the international scene.

**Figure 1: Drug connections on the international scene**  
**Source: (Hubschle, 2011: 28).**

Nations with strict measures on illicit narcotics to a large extent have been greatly hit by such measures; this is following the high rate at which such measures are breached. Equally, those local economies on the receiving end such as Ecuador have been hardly hit by issues arising from drug prohibition and its trade (Hubschle, 2011: 25-40). In the contemporary world, the business scene is that of integration, where legitimate businesses are established using illegal activities funds such as illicit narcotics trade. This is the situation where, the gains realized from trade in illicit narcotics for substances such as cocaine as well as opium are utilized by transnational criminal groups to diffuse, contaminate as well as disrupt the well functioning of power structures likewise the economy at large (Sherman, 2010: 7-15). Also, illicit drugs trade are associated with the armed differences worldwide, such as in some West African States, where civil wars have been directly or indirectly linked to illegal drugs trade for instance in Angola among many other nations worldwide (Birdsall, 2008: 203-229).

Often, with probable financial challenges within various economies, such situations create more openings for those who rely on the formal economy, basically to take part in illegal economic activities, ostensibly to settle losses incurred during periods of financial difficulties (Storti and Grauwe, 2011: 23- 45). The fact is that, illicit drugs trade is highly profitable, besides being hard to keep under surveillance for purposes of market regulation. Again, with its' widespread reach as well as its' effects that are largely downplayed, its role in each economy on the global front especially on supplier nations along with transitory nations does not garner the attention it deserves (Jenner, 2011: 901-927).

As of 2010 (Scott and Marshall, 1998: 34-67) indicates that drug seizures had declined a great deal owing to the extensive media focus on issues to do with illicit narcotics trade. This was also supported by the well orchestrated actions of nations in different parts of the world likewise concerned international bodies, for instance

the United Nations office (UNODC) that is charged with the responsibility of dealing with drugs as well as crime. Even so, the fall in captures of illegal drugs do not imply that such transactions have significantly dropped; this only indicates that illicit narcotics cartels along with contrabandists have turned out more advanced in their techniques and ways of transporting likewise of selling them. Furthermore, in relation to drugs seizures (Jenner, 2011: 901-927) reports that most of the trade routes together with transportation techniques of illicit narcotics have been greatly repositioned. This is evident to the hardihood as well as advancement of parties to this trade, besides the resilience of the illegal drug cartels in evading being caught (Storti and Grauwe, 2011: 23- 45).

Lately it has come out that local players along with criminal connections are taking over more elaborate systems, to secretly trade in illicit narcotics. This take over is a denotation of how the illegal trade is well linked in the international economy. As such connections have enabled parties into the illicit narcotics trade to be way ahead of the organizations dealing with drug crimes as well as global efforts to eradicate this trade (Scott and Marshall, 1998: 34-67).

As pointed out in (Mamdani, 2004: 12-23), some of the well-known illicit narcotics often traded in the global market include the following; top on the list cocaine, which mainly comes from Colombia as well as Bolivia and is exported to other parts all over the world. The second drug is cannabis, which is also widely available as well as traded because of its medicinal value besides its recreational use. This drug is allowed in economies like Canada, yet also prohibited in other countries because of its negative effects. The third drug most traded in the global scene is tobacco that despite being legally allowed for use by adults, it is highly taxed pushing it to the black market, where users are able to purchase it at relatively low prices (Hubschle, 2011: 25-40).

The third illicit drug as discussed in (Jenner, 2011: 901-927) is heroin, which is mainly from Mexico along with Southeast Asia region, and has more attractive sales returns when compared with most of the other illicit narcotics. Fourth is methamphetamine along with Temazepam, both of which are mostly prepared in laboratories among many other techniques. On average, in the global economy there are more than four hard drugs that are highly profitable to traffickers, and though illegal continue to make it to various regions of the world to meet the addiction needs of their users. Generally, some of the means employed to transport these drugs include air transport like use of cargo planes and water transport using container ships besides use of human agents either through agreement or at times through coercion. This is mainly done through coordinated efforts of political leaders from various countries around the world (Scott and Marshall, 1998: 34-67).

### **Effects of Illicit Drugs Trade**

The illegal narcotics business undeniably according to (Ellis, 2009: 26-35) is one of the biggest black market sectors in the global arena, with its high profit returns; hence it comes very close to the legal emerging economies just like in Latin America. Unfortunately, Latin America is susceptible to extensive capital flight, majorly because of its highly forceful entrepreneurs coupled with the drug barons and many others. For the most part, as a result of trade in illicit narcotics, the global economy continues to face numerous challenges resulting from ceaseless chaos of masterminded drug crimes, where those mafias collect government revenues like taxes for their own selfish interests (Mamdani, 2004: 12-23).

In reality, there are a range of effects inherent in illicit narcotics trade on the global economy, effects that touch on crucial economic factors linked to production as well as consumption and distribution such as labor force besides security among others (Hubschle, 2011: 25-40). The illicit narcotics trade as pointed out in (Jenner, 2011: 901-927) has developed to a level that is sabotaging the main economic framework. This implies that, this black market of illicit narcotics is endangering the extent at which the global economy is developing.

The first effect is that, trade in narcotics coupled with their use leads to destruction of human capital, and even worse the society's well functioning (Ellis, 2009: 26-35). In other words, trade in illicit narcotics coupled with their abuse as discussed in (Storti and Grauwe, 2011: 23- 45) in the long run causes falling apart as well as disorganization of social set ups. This happens quite often to economies that largely rely on such illegal activities. Acts that without doubt trigger the disentangling of its people and society values, values that are necessary for not only survival but also social likewise economic cohesion. Apparently, once the individuals in an economy become weak, particularly from use of illegal drugs, there are high chances that insecurity issues will result in the global economy, following the dependency and poverty levels and even crimes among many other social issues. Such kind of insecurity trends are aggravated by negative effects of illegal drugs trading accompanied with drug use (Scott and Marshall, 1998: 34-67).

The second effect is that, in illicit narcotics trade passing illegal drugs via a country implies that most of it is retained within that economy. Such drugs are possibly dispensed as a settlement for the services offered or as a point of profit for the local agents, the impact being more usage of such drugs hence paralyzing several economies and wider distribution channels. The third effect is that, with illegal drugs trade the desire to get education is overwhelmed by the mindset of individuals wanting to acquire wealth within a short period, especially among the young population (Mamdani, 2004: 12-23). Such a situation in turn affects the global economy by lowering quality of the workforce, and ultimately employee productivity levels. Also, the moneymaking chances, power and high returns linked to illegal drugs trade turns out more appealing to marginalized groups like the youth, distracting them from acquiring crucial working skills. In that way, the skilled workforce reduces and those available can only carry out less production activities which in turn affects overall global productivity (Jenner, 2011: 901-927).

Fourthly, illicit narcotics leads to a rising number of unskilled and unproductive as well as unemployed people in an economy who are most likely to abuse the illegal narcotics themselves, hence enlarging the drug use practices in an economy. This also takes place as some of the drugs are linked to health issues the spread of other infectious diseases such as HIV mainly through sharing of injections (Scott and Marshall, 1998: 34-67). On the other hand, in the global economy, drug crimes encompass a wide range of underground activities inclusive of human and dangerous weapons trade. The kind of underground activities that in one way or another curtail the progress of world economies, as they subvert governing standards, human rights and overall health. With such effects, illegal drugs trade act as a kind of a destabilizing power more so for fragile developing economies (Ellis, 2009: 26-35).

Additionally, the high amount of foreign exchange as a result of illegal drugs trade revenues can cause currency overvaluation likewise loss of competitiveness for exports and domestic production, which competes with imports among much other

disorganization in business operations (Mamdani, 2004:12-23). Moreover, illicit narcotics trade leads to a declining as well as sabotaged work force, besides influencing formation of a divided legal structure. Also, illegal drugs trade forms a good ground for constant violence among members of the society, where organized criminal activities accompanied with corruption creates a risky business environment. Likewise, with illegal drugs trade there is a ***potential of having slow economic progress as people's behaviours change drifting from performing productive economic activities to non productive ones. This situation has high chances increasing the cost of operating a formal economy, especially if there are high cases of*** incarceration as well as homicide among many others (Jenner, 2011: 901-927).

***Furthermore, if illegal drugs revenue tends to be concentrated in particular economies of the world, this has caused unequal development of regions. This is the case as the illicit trade in narcotics induces*** regional booms as well as busts that possibly hurt the global economy (Mamdani, 2004:12-23). ***In a way, this illegal drugs trade encourages money laundering, an act which exaggerates consumption along with trading patterns as drug dealers and their partners utilise money gained from such activities to invest in other sectors of the global economy like real estate and capital intensive ventures. Also, illegal drugs markets create a massive number of jobs for societies particularly for the suppliers and sellers, increasing income expectations for the local economies*** (Scott and Marshall, 1998: 34-67).

Apparently, most money laundering activities linked to illicit drugs trade take place not only in offshore, but also involving professionals such as accountants and many others. Taking the case of Guinea - Bissau, security officers are used to execute most of the illicit narcotics businesses, especially transportation (Mamdani, 2004:12-23). Indicatively, the illegal drug business transactions according to (Jenner, 2011: 901-927) are taking away the economies' commitment to boost legitimate operations. Which can be translated as foreclose for the growth of normal economic organizations as illegal drugs trade weakens political as well as social institutions. Undeniably, the detrimental economic effects of illicit narcotics trade are far much than the direct costs for rebuilding the destruction emerging from this trade. This takes into account the escalating expenses for medical as well as policing and social costs. This basically extends to the disintegration of efficacious operation of the global economy, causing the expenditure on crime prevention to turn out as a form of tax (Jenner, 2011: 901-927). Furthermore, illicit narcotics just like lawful alcohol, either directly or indirectly degrade the essence of the labor force. The policing issues emerging on the global economy from narcotics trade is that, much more resources are directed towards other expensive miscellaneous expenses, resources which could otherwise be utilized for other more productive uses (Scott and Marshall, 1998: 34-67).

## **Conclusion**

From the above discussion, it has emerged that the scope as well as scale of illicit drugs trade has made most of the international organizations and law keeping agencies to get concerned on the possibility of illicit narcotics trade getting out of hand. Generally, the presence of illegal drugs is apparent in the modern society, with players in the illegal drugs sectors turning out more powerful than a number of

government agencies considering the numerous amounts of money they derive from such transactions. Some of the major effects of illegal drugs trade which impact the global economy are related to profits made from such activities along with the possibility of violence and their destructive effects on people's health. In the event that such situations arise in the global business environment, such conditions have high probabilities of discouraging economic progress. Hence a need for various economies to join efforts to establish a favorable global political likewise economic environment, that promotes economic progress. More importantly, to effectively address negative economic issues linked to illegal drugs trade, there is apparent need for integrated efforts from various players in the global economy. Such efforts are chiefly to minimize not only the harmful effects resulting from the use of illicit narcotics, but also from the trade itself and to build sustainable economies.

### **Acknowledgements**

I am very much humbled by the valuable support coupled with constructive criticism that I received from my Professor / Rodica Milena Zaharia, PhD, Academy of Economic Studies, Bucharest, Department of International Business and Economics. which has enabled me to learn a lot in my academic endeavors.

# WEAK EFFICIENCY AND LINEAR REGRESSION OF CENTRAL AND EASTERN EUROPEAN MARKETS

**Azat Davtyan**

*Department of Finance, Faculty of Economics and Business Administration, West University of Timisoara, Timisoara, Romania  
azaartashes87@gmail.com*

**Abstract:** *The deepening of financial integration in the EU has accelerated in the last decade. The expansion of trade relations, intensification of investment flows and capital market development evidence strengthening of financial integration processes. Particularly, the large number of foreign companies listed on domestic equity market enhances financial integration. In this regard, the enlargement of stock markets of Central and Eastern European (CEE) countries and efficient capital allocation define further integration prospects.*

*The stock market efficiency depends mainly on adequate pricing of capital and risk. The rational investment expectations and information efficiency positively impact trading strategies and eliminates the presence of undervalued and overvalued assets. This leads to the high competitiveness of stock market and decreases the likelihood of abnormal profits.*

*Studies of stock market efficiency of CEE countries and the correlations of CEE capital markets with Western European markets have a significant importance owing to the ongoing financial integration and impact of financial crisis. I run two tests to check the capital market efficiency of CEE countries taking into account the perspectives of CEE countries to enter the euro area.*

*The aim of this quantitative empirical research is twofold: first, it investigates the weak form of market efficiency for the period from 2<sup>nd</sup> of September 2005 to 31<sup>st</sup> of August 2011 by using the Augmented Dickey-Fuller and Kwiatkowski-Phillips-Schmidt-Shin unit root procedures. Second, it checks the existence of linear correlation between CEE countries and Western European markets.*

*The results assume that the stock markets of some CEE countries follow a unit root. The linear regression model evidences different correlation patterns between CEE and EU old capital markets.*

*Those findings can be used for deeper investigation of market efficiency by highlighting convergence processes of CEE countries with EU old member states. Also effective capital allocation channels, institutional foundations of markets and strengthening of corporate governance should be highlighted. Finally, the outcomes of my paper will be useful for researchers in the field of finance.*

**JEL classification:** *G10; G14*

## **Introduction**

The financial integration of CEE markets fosters the strengthening of information efficiency in these markets. This factor improves the risk-sharing and diversification of capital. In other words, market efficiency shows the degree of development of equity market assuming effective asset allocation, pricing and good governance. In market efficiency environment investors have an opportunity to largely diversify their

funds. Market efficiency fosters effective investment decisions in real economy which support an economic development of country. Basse (2010) assumes that under conditions of market inefficiencies, designing (high cost) sophisticated trading rules based on publicly available information will systematically yield significantly positive abnormal returns to investors.

Following section covers empirical methodology. I discussed in detail the Augmented Dickey-Fuller and Kwiatkowski-Phillips-Schmidt-Shin tests. The third section reports the results of study. The last section concludes.

I emphasize the findings of other authors. In particular, Rockinger and Urga (2000) show that both Czech and Hungarian stock returns were mostly correlated with German market movements. Nivet (1997) supposes that the Polish stock market do not follow a random walk. A similar study was carried out by Divis and Tepy (2006) for testing the random walk hypothesis for CEE markets. They assume that Hungarian, Polish, Czech and Slovakian stock markets show a random walk. Ratkovicova (1999) approves the strong correlation of Hungarian stock prices with DAX. Besides, the reported results assume the presence of unit root of Hungarian, Polish and Slovakian indices except for the Czech index. Hasanov and Omay (2007) find that stock prices of Bulgarian, Czech, Hungarian, Polish, Romanian and Slovakian markets show a weak form efficiency. Those authors also indicate that nonlinear unit root test results assume the acceptance of unit root test at conventional levels for the Bulgarian, Czech, Slovakian and Hungarian stock prices. The ADF test conducted by Omay and Karadagli (2012) indicate that Bulgarian, Hungarian, Russian, Polish, Slovenian and Romanian stock price series follow unit root.

### **Empirical Methodology**

Any sequence that contains one or more characteristic roots that are equal to one is called a unit root process. The simplest model that may contain a unit root is the AR(1) model.

Ssekuma (2011) thinks over the autoregressive process of order one as:

$$Y_t = \varnothing Y_{t-1} + \varepsilon_t \quad (1)$$

where  $\varepsilon_t$  denotes a serially uncorrelated white noise error term with a mean of zero and a constant variance.

If  $\varnothing=1$ , equation (1) becomes a random walk without drift model that is, a nonstationary process. When this happens, we face what is known as the unit root problem. This means that we are faced with a situation of nonstationarity in the series. As Ssekuma (2011) finds that if  $\varnothing<1$ , then the series  $Y_t$  is stationary. On the other hand, Yule (1989) supposes that the stationarity of the series is important because correlation could persist in nonstationary time series even if the sample is very large and may result in what is called spurious (or nonsense) regression.

The presence of serial correlation in the residuals of the Dickey-Fuller test biases the results. For that reason the ADF test was developed. The idea is to include enough lagged dependent variables to rid the residuals of serial correlation (Mahadeva and Robinson, 2004). The basic idea behind the augmented Dickey-Fuller (ADF) test for nonstationarity is to simply regress  $Y_t$  on its (one period) lagged value  $Y_{t-1}$  and find out if the estimated  $\varnothing$  is statistically equal to 1 or not. Equation (1) can be manipulated by subtracting  $Y_{t-1}$  from both sides to obtain (Ssekuma, 2011):

$$Y_t - Y_{t-1} = (\delta - 1) Y_{t-1} + \varepsilon_t \quad (2)$$

which can be written as:

$$\Delta Y_t = \delta Y_{t-1} + \varepsilon_t \quad (3)$$

where  $\delta = (\delta - 1)$ , and  $\Delta$  is the first difference operator.

In practice, instead of estimating equation (1), we shall estimate equation (3) and test for the null hypothesis of  $\delta = 0$  against the alternative of  $\delta \neq 0$ . If  $\delta = 0$ , then  $\delta \neq 1$ , meaning that we have a unit root problem and the series under consideration is nonstationary (Ssekuma, 2011). Erdogdu (2007) assumes that under the null hypothesis  $\delta = 0$ , the t-value of the estimated coefficient of  $Y_{t-1}$  does not follow the t-distribution even in large samples. This means that the t-value does not have an asymptotic normal distribution. The decision to reject the null hypothesis of  $\delta = 0$  is based on the Dickey-Fuller (DF) critical values of the  $\tau$  (tau) statistic. The DF test is based on an assumption that the errors of term  $\varepsilon_t$  are uncorrelated (Ssekuma, 2011). Syczewska (2010) indicates that the Kwiatkowski-Phillips-Schmidt-Shin (KPSS) test has a null of stationarity of a series around either mean or a linear trend; and the alternative assumes that a series is non-stationary due to presence of a unit root. Moreover, in the KPSS model, series of observations is represented as a sum of three components: deterministic trend, a random walk and a stationary error term. The model has the following form (Syczewska, 2010):

$$\begin{aligned} y_t &= \xi t + r_t + \varepsilon_t \\ r_t &= r_{t-1} + u_t \end{aligned} \quad (4)$$

where  $y_t$ ,  $t=1,2,\dots,T$  denotes series of observations of variable of interest,  $t$  – deterministic trend,  $r_t$  – random walk process,  $\varepsilon_t$  – error term of the first equation, by assumption is stationary,  $u_t$  denotes an error term of second equation.

Syczewska (2010) shows that the null hypothesis of stationarity is equivalent to the assumption that the variance  $\sigma_u^2$  of the random walk process  $r_t$  in equation (4), equals zero. In case when  $\xi=0$ , the null means that  $y_t$  is stationary around  $r_0$ . If  $\xi \neq 0$ , then the null means that  $y_t$  is stationary around a linear trend. If the variance  $\sigma_u^2$  is greater than zero, then  $y_t$  is non-stationary (as sum of a trend and random walk), due to presence of a unit root.

Syczewska (2010) subtracts  $y_t$  from both sides of the first equation in equation (4) and obtain:

$$\Delta y_t = \xi + u_t + \Delta \varepsilon_t = \xi + w_t$$

where  $w_t$ , due to assumption that  $\varepsilon_t$ , and  $u_t$ , are independently distributed random variables, is generated by an autoregressive process AR(1) (Kwiatkowski et al., 1992):  $w_t = v_t + \theta v_{t-1}$ . Hence Syczewska (2010) mentions that the KPSS model may be expressed in the following form:

$$y_t = \xi + \beta y_{t-1} + w_t$$

$$w_t = v_t + \theta v_{t-1}, \beta=1$$

According to Tranmer and Elliot (2008), the multiple linear regression represents  $p$  explanatory variables, and the relationship between the dependent variable and the explanatory variables is represented by the following equation:

$$y_i = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_p x_{pi} + \varepsilon_i$$

where  $\beta_0$  is the constant term and  $\beta_1$  to  $\beta_p$  are the coefficients relating the  $p$  explanatory variables to the variables of interest.

I emphasize the main characteristics of the linear regression model. The latter includes (Nathans et al., 2012):

- The correlation coefficient reflects both the magnitude and direction of the relationship between two independent variables. If a correlation coefficient is negative, the value of the variables that are correlated are inversely related; as one variable's scores increase the other variable's scores decrease. If a correlation coefficient is positive, an increase (or decrease) in one variable is related to an increase (or decrease) in the other variable in the coefficient.
- The closer the value of the correlation coefficient is an absolute value of 1.0, the larger the magnitude of the relationship is between the two variables. If the value of the correlation coefficient is zero, there is no relationship between the two variables.
- It is important to note that the strength/magnitude of a correlational relationship is not related to the sign of the correlation coefficient; thus, equivalent predictive power can be attributed to correlations of equivalent magnitude but different signs.

### Empirical Findings

In this study I use stock market data (from 2<sup>nd</sup> of September 2005 to 31<sup>st</sup> of August 2011) of CEE countries and EU old member states. Particularly, I examined the ADF and KPSS tests for Bulgarian (SOFIX), Hungarian (BUX), Polish (WIG), Romanian (BET) stock markets.

The results of ADF and KPSS tests for CEE stock market returns are shown in tables 1-8. As can be seen the null hypothesis of random walk is accepted for BET, WIG and BUX stock indices. I reject the null hypothesis for SOFIX.

I find different correlation patterns between the old and new stock markets of the EU (Table 9). In particular, some of CEE markets are negatively correlated with EU old capital markets. This mainly refers to BUX and BET. BET is in negative relationship with CAC40, DAX and IBEX. WIG and SOFIX are not correlated with most of developed markets.

### Conclusion

This paper investigates the random walk hypothesis of CEE stock markets by using the Augmented Dickey-Fuller (ADF) and Kwiatkowski-Phillips-Schmidt-Shin (KPSS) tests. Besides, we checked linear regression between CEE and EU old member countries' markets.

From the ADF and KPSS tests I get mixed results. Particularly, BET, WIG and BUX follow a random walk hence these markets are weak efficient. The null hypothesis of random walk is rejected for SOFIX.

I assume that CEE markets have different correlation patterns with Western European markets. The CEE markets are negatively correlated or not correlated with European developed markets.

The outcomes of my study can be summarized as follows: Romanian, Polish and Hungarian stock returns follow a random walk according to the ADF and KPSS tests and WIG, BET, BUX and SOFIX are not positively correlated with European developed markets.

I find that the deepening of capital markets assumes a high transparency of market information and robust relations between market players. In this regard, the information efficiency depends on several factors. Particularly, the introduction of new trading platforms and systems enhances the efficiency of firm-level and market-level efficiency of firm-level and market-level information. By contrast, restrictions imposed on short sales and price limits hinder information efficiency. Market efficiency is also conditioned by the relationships of managers and investors. Thus, the intention of managers disclose or not firm-specific information impacts credibility of investors.

In general, it appears that the weak efficiency of Polish, Romanian and Hungarian equity markets is conditioned by good supporting institutions and governance and developing investor protection regulation and increasing transparency. On the contrary, the capital market infrastructure of Bulgaria seems to be underdeveloped which undermines the stock market efficiency.

# TECHNICAL AND FUNDAMENTAL ANOMALIES. PARADOXES OF MODERN STOCK EXCHANGE MARKETS

**Bako Elena – Dana, Sechel Ioana-Cristina**

*Babeş - Bolyai University, Faculty of Economics and Business Administration, Cluj-Napoca, Romania*

[dana.bako@econ.ubbcluj.ro](mailto:dana.bako@econ.ubbcluj.ro)

[isechel@yahoo.com](mailto:isechel@yahoo.com)

**Abstract:** *This paper continues the series of researches about the paradoxes of modern stock exchange markets and their impact on the real economy, addressing this time the most important technical anomalies but also fundamental anomalies, which can be observed on the financial markets. As we mentioned in several previous articles, the paradoxes of stock exchanges are related to potential contradictions that arise in relation to a generally accepted truth. A lot of researches in the field of stock market investment focused on finding the answer to the question whether historical prices can be used to predict future prices for listed securities. Complex forecasting methods were created to clarify this aspect. Thus, technical analysis is a method of forecasting the price movements and trends of the market in the future, by studying the market graphs (including here both, the price of the listed instruments and the volume of transactions). The fundamental anomalies refer to the anomalies in trading financial instruments, and to the elements of fundamental analysis. The basic principle of fundamental analysis refers to the fact that the market price of any financial instrument is the result of supply and demand for that instrument. Both the supply and demand that finally determine the price of a financial instrument, are under the influence of various factors. Market's analysts monitor various economic indicators and examine the market reports, to detect changes that may occur in the economy. The fundamental analysis attempts to predict prices and the overall market development by analyzing some economic indicators, political or social factors which are likely to influence the stock exchange prices. Both technical and fundamental anomalies have a major impact on price formation for financial instruments which are traded on stock exchanges, and are able to offer to warned investors higher earnings.*

**Keywords:** *stock market paradox; technical anomalies, fundamental anomalies, trend lines.*

**JEL classification:** *G02; G12; G23;*

## **1. Technical anomalies**

Technical analysis sets its beginnings in the work and theories of Charles Henry Dow, its fundamental principles referring to the fact that:

- Market actions update everything - the price of listed financial instruments seen as the intersection of the supply and demand for such securities reflects through its value the influence of various factors. The purpose for technical analysis is not to identify the factors that influence the price, but only the price movement and its analysis in time.

- The existing configurations - Technical analysis attempts to give models of the evolution of market prices based on historical data, so these configurations offer some probability that certain results can be expected.
- The history tends to repeat itself - graphics configurations proposed by technical analysis tend to repeat over time due to the characteristics of human psychology.

Technical analysis involves besides many advantages also many disadvantages demonstrated in time (Reuters, *Introducere în studiul analizei tehnice*, 2001, p. 22). From the most important positive aspects that technical analysis involves, we can include the followings:

- It can be used for a wide range of financial instruments listed on every market. Hence a very important feature of technical analysis, namely the flexibility. Technical analysis can easily be adapted to different products traded or different types of markets, the principle remains the same.
- Graphical representations of the evolution of equity prices can be realized for different periods: for hours to historical data for decades - this is because of the technology used (computers).
- In time, a development of the instruments that are used in technical analysis could be noticed. We could say that these instruments are innovations of research in this area.
- The data used by technical analysis are historical data, but recent years technology has allowed even the use of real time data to conduct technical analysis (or with a subtle delay).

Of course, the technical analysis involves a series of disadvantages, most important of them being related to:

- Due to the fact that technical analysis is realized by analysts, who are human beings, the subjective factor is not eliminated. In fact, this is the biggest disadvantage of technical analysis, meaning that forecasts based on the data analysis rely heavily on the subjective factor - the way the same data are differently interpreted by various analysts.
- The technical analysis is based on the extrapolation of events and the moving quotations in time. This is a subject of probability theory, the future and upcoming events being unknown to mankind. Technical analysis addresses an issue so long coveted by mankind: knowing the future.
- Regarding the probabilistic nature of the evolutions that technical analysis is studying, we can say that it is concerned with determining the probability of stock market quotations, and not concerned about the certainty that they will come true.
- Information used by technical analysis can be sometimes wrong, or less accurate, which distorts also the result (as forecast).

The main elements technical analysis is based on are: the prices of financial securities, the repeatability of price trends in the market, and the fact the prices tend to enroll in some trends.

The opponents of the results' accuracy obtained using technical analysis bring as an explanation the random walk theory and the theory of confirmed projection. *The random walk theory* was first discussed in the research filed by Jules Regnault, a French broker in 1863. Later, in 1900, the theory has gained new dimensions in terms of the interpretation by Louis Bachelier in his doctoral thesis, then the subject

is approached by Cootner Paul (1964), Burton Malkiel (1973) and Francis Eugene Fama (1965). According to the random walk theory, the future prices of listed financial securities can not be determined or predicted, because they have a random evolution to their intrinsic value. The theory of confirmed projection highlights the subjective interpretation of graphs.

Technical analysis tries, using historical prices and statistics with this regard, to forecast future prices of the listed financial securities. The simplest techniques and trading strategies are based on a classical graphical analysis, which includes the interpretation of straight trend of building configurations or reversibility, the lines of support, the lines of resistance, moving averages or gaps. More complex techniques include in the analysis indicators like: RSI (Relative Strength Index), stochastic oscillators, moving average convergence-divergence or elements of Elliott wave theory, Fibonacci numbers and Gann graphics.

### **1.1. Elements of simple graphical analysis**

The simple graphical analysis involves the analyst interpretation of the trend lines (straight trend), of building configurations or reversibility, the support lines or resistance lines, moving averages or gaps that can be seen or built on financial securities price trends. Their purpose is very clear: to determine the most appropriate moments to sell or to buy securities in the market, at the best price.

**The trend line** is given by consecutive points, the minimum or maximum price of financial securities or the value of a stock index, its purpose being to identify the direction of market trends or the trend for the price of listed securities. The trend lines are used to identify market direction or the moment of its reversal. If the trend line is supported by a large number of intermediate points, the trend is stronger, and if it entails some interruptions, the signal refers to a possible change of the trend.

**Building configurations** are regular shapes identified in the graphic evolution of securities prices or of the market prices as a whole, in form of triangles, quadrilaterals or flags. These forms are quite difficult to identify and once prices evolve out of the parameters of these forms they give investors entrance and exits signals from the market.

**Configurations of reversibility** indicates the minimum and maximum levels of prices, correlated with the possibility of trend reversal. They are easy to identify if they are based on a strong trend, because at least visually, their identification is easier. The most important reversible formations are: head and shoulders, top and bottoms (maximum and minimum), wedges.

**The support lines and resistance lines** are perhaps the most important technical elements used by technical analysis. The support line of a graph is given by the minimum levels of prices in the market. This can be interpreted as the minimum price where the interest of buyers is strong enough to face selling pressure. Support line has this name due to the fact that the market doesn't fall below it. The support line is adjusted whenever the price falls to a lower level compared to the last value.

The resistance line can be seen in opposition with the support line, it is given by the maximum level prices in the market could reach. Resistance line can be interpreted as the level where selling interest is strong enough to face the pressure of buyers.

**Moving averages** - using moving averages is a method of smoothing the historical data, the purpose of their use being to confirm the price trends. Moving average may take into consideration the price variations for different periods of time as follows: if

the aim is a short-term analysis the data used will be for 9 or 10 days, 18 to 20 days, and if the aim is a long term analysis, it will be taken into account prices on 50,100 or 200 days. The most common used moving averages are simple moving averages (SMA - Simple Moving Average), weighted moving average (WMA - weighted moving average) or exponential moving averages (EMA - exponential moving average). Besides the fact that moving averages confirm the trend, they help investors identify the buying signals and the selling signals in the market.

**Gaps** are graphical configurations which are used to determine and confirm price movements. For example, a gap is formed when the minimum price of a financial instrument in a given period is higher than the highest price of the previous period, or vice versa (Reuters, *Introducere în studiul analizei tehnice*, 2001, p. 116).

### **1.2. Complex elements of technical analysis**

In addition to simple constructions of graphs highlighting the evolution of prices over time, correlated in many cases with trading volumes, technical analysis uses a number of indicators to confirm trading strategies based on graphs. The two main categories of indicators, which refer the technical analysis, are:

- Confirmation indicators or divergence indicators - with their help, the trends can be confirmed, the divergent evolution of the indicator to the price evolution is considered as warning signal. Parts of this type of indicators are the trading volume and moving averages.
- Momentum indicators or oscillators - they measure the frequency of price movements to the price level and are used to establish different trading strategies. Part of this category is the relative strength indicator (RSI), the stochastic oscillator or moving average convergence-divergence (MACD-Moving Average Convergence Divergence)

Without insisting on the method of calculation of these indicators and on the ways this results are use and interpreted, we can say that in time it has been shown that some price evolutions tend to recur. Of course, no graphic format looks exactly the same like another and the accuracy of prediction lies in the eyes of someone who interprets the results and sees that essential required to issue a forecast. Using information from the past (historical prices) method on which the technical analysis is based, is widely used in many other areas. In other words, the future behaviour of a market is also given by its history.

## **2. Fundamental anomalies**

Fundamental anomalies refer to anomalies in trading financial instruments, to elements of fundamental analysis. The basic principle of the fundamental analysis refers to the fact that the market price of any financial instrument is the result of supply and demand for that instrument.

### **2.1. The value**

Seen as a factor of influence in trading financial instruments, their value seems to be the most important anomaly which is commonly used in setting the investment strategy of market actors. Essentially, this anomaly consists on the fact that investors tend to wrongly overestimate the growth prospects for the companies and to underestimate the value of companies. In a work of reference for this anomaly, Lakonishok concluded that "trading strategies that are based on value, offer a high

yield because they take advantage of ordinary investor mistakes, and not because they were fundamentally speaking, more risky" (Lakonishok, Shleifer, & Vishny, 1994).

The issue of value in determining the investment strategy has been addressed by many researchers over time. Thus, (Chan & Lakonishok, 2002) reviewed the literature with respect to performance value due to the growth strategies. The conclusion they arrived to, was that the size of risk is not the result of the fact that differentiated yields are due to higher risk assumed, but rather is due behaviour reasons or transaction costs incurred. We believe therefore that the subjective factor as emotions, temperament or attitude, in this case has an important role in determining the investment strategy.

Supporters of investment strategies based on growth, analyse how the value and its growth are influenced by some factors. Their findings show that growth fund managers have been more successful than managers managing value-based financial instruments.

## **2.2. Low price to book**

Eugene F. Fama and French conducted in 1992 a study on the performance of the financial instruments with low price on the market (Eugene & French, 1992). Their study has focused on the period between 1963 and 1990 and took into account almost all securities listed on NYSE, AMEX and NASDAQ. At the initial stage, securities were divided into 10 groups, which were to be rerouted every year. Yields obtained by the cheapest titles far exceeded the yields obtained by more expensive securities, namely 21.4% in the first case and 8% for the last. The same study reflects the fact that authors divided financial instruments into groups based on beta coefficient, reaching the conclusion that securities with greater value were associated with lower risk compared to the growth ones. Seen from this perspective, the value receive connotations of risk, thus the value is a risk factor for which the investors will be rewarded with an additional return if they will assume it.

Therefore, we can say that paradoxically, securities with lower prices in the market offers the possibility of obtaining higher annual returns than securities more valuable.

## **2.3. Other fundamental anomalies**

Patel, Yao and Barefoot showed in 2006 that financial securities that offer high dividend yields have given better performance (from the perspective of market price) than financial securities offering lower dividends yields (Patel, Yao, & Barefoot 2006).

There are investors who use as an investment strategy the technique "against the market". This means that they will select for their portfolios, securities most neglected on the market (the less traded). The technique was demonstrated in 1970 by Werner DeBondt and Richard Thaler that through a study concluded that the highest performance is achieved by the neglected securities of the market, their yields are higher than the overall average of the market .

## **3. Another anomalies on financial instruments trading**

### **3.1. Size effect**

The size effect was studied for the first time by Banz in 1981, studies he conducted for New York market showed that the profitability achieved by small capitalization

companies is on average higher than the return obtained by large capitalization companies, (Simon, 1997, p 425). Banz divided all the listed shares on the NYSE into five classes according to the market capitalization of the companies and analyzed the evolution of their returns for the period from 1926 to 1980. The conclusion he reached is the fact that yields obtained by the smallest companies (with the smallest market capitalization) were superior to other classes of companies with high market capitalization. Yields obtained by them were even higher than the market average (than the index performance) (Banz, 1981).

The phenomenon has been studied by other researchers: Ibbotson in 1984, Reinganum in 1981 or Lamoureux and Sanger in 1989, these studies refer to securities listed on the American Stock Exchange.

In a 1997 article in Forbes magazine, Mark Hulbert contradicts the so-called myth of small capitalization (small cap myth) considering that there is no advantage for those who choose to invest in the securities of small capitalization companies (Forbes, 2012). Hulbert specifies that the study undertaken by Banz in 1981 did not take into account the transaction costs, which in the case of securities of small capitalization companies can be significant. Also Hulbert believes that the size effect proposed by Banz can not be extended to all world stock markets because the study was conducted exclusively using data from the U.S. stock markets, where small capitalization companies have actually a much higher capitalization than large capitalization companies whose securities are listed on other stock exchanges of the world.

### ***3.2. The effect of announcements on the price***

The announcements effects on prices in the market show that price changes tend to persist even after the initial announcements. Securities for which the announcements made are positive, tend to move upward, and securities for which the announcements are negative, tend to move downward. The essence of this effect is that securities with a consistent growth will grow even more, despite the fact that initial increases were above market expectations. Conversely, if the securities price encounter a steady fall, it will fall further, even if the initial decreases were higher than investors' expectations. The effect of announcements on the price is known as the paradox of high-higher or low-lower.

### ***3.3. IPO's effect on the price***

Numerous studies have concluded that initial public offerings have as an effect a drop in prices on the market, thus achieving poor performance for the companies concerned. The phenomenon is seen as an evidence of market inefficiency by Dharan and Ikenberry. They showed in a study that companies listed on the NYSE and AMEX for the first time (via an initial public offering) obtain lower performance than companies already listed (Dharan & Ikenberry, 1995).

### ***3.4. Insider trading effect***

Transactions made by insiders refer to deals based on inside information. This information has a distinct nature, has not been made public and regards an issuer (company) or certain financial instruments. If this information would be conveyed to the public, it could significantly affect the market value of securities. Trading on such information is an abuse on the market and is sanctioned by supervisors.

On this subject, there are numerous studies referring to the link between transactions carried out by staff of listed companies (company directors, managers or anyone who has access to inside information) and the performance of those securities. In terms of trading on inside information it is considered that if much more such insiders will buy lots of company's shares where they are employed, it is an important signal to all other market participants. In such cases, insiders believe that there is a significant probability that the price of these securities to increase in the future.

## 2. Conclusion

Anomalies in trading financial instruments are associated with the moments when securities prices deviates from their normal behaviour, creating opportunities for those who identify them. These can be viewed from the perspective of time, in which case we can talk about calendar anomalies. From the perspective of interpretations that technical analysis involves, we can talk about technical anomalies, and from the perspective of the interpretations given by the fundamental analysis, we talk about fundamental anomalies.

Technical analysis through which there can be identified technical anomalies, involves interpretation of graphic configurations and price movements and the combining of these formations with the interpretation of some indicators like stochastic oscillator, moving averages, Elliot wave and Fibonacci numbers.

Fundamental anomalies are based on the interpretation of fundamental analysis. Analysts monitor various economic indicators and speculate possible market reversals trends that occur due to changes in the economy.

## **BUSINESS ETHICS IMPLEMENTATION IN THE ORGANIZATIONAL CULTURE OF COMPANIES**

**Berinde Mihai, Andreescu Nicoleta Alina**

*Faculty of Economic Sciences, University of Oradea, Oradea, Romania*

[mihai.berinde@yahoo.com](mailto:mihai.berinde@yahoo.com)

[nandreescu@uoradea.ro](mailto:nandreescu@uoradea.ro)

**Abstract:** *In this paper we have analysed the perception and implementation of the principles of business ethics for companies.*

*This paper is a theoretical approach to ethical principles and the corresponding legislation, as well as an analysis of the degree of alignment of national legislation with the latest stipulations following the entry into force of the UK Bribery Act. This Act is currently recognized as a new and more comprehensive approach on the subject of ethics in international affairs.*

*At the same time, this paper focuses on the study case regarding the comprisal of Business Ethics principles within the activity of Romanian companies. Therefore, a practical approach is achieved, with an applicability of the theoretical aspects, which are the subject of the first part of this paper.*

*We analysed the need to implement Codes of Ethics and their advantages. Companies that do business with an organization that has implemented a Code of Ethics should be aware of its provisions and act accordingly, because it is a mandatory issue for all employees, and also in its relationships with the external stakeholders.*

*A code of ethics is a tool, a means of transmitting the organizational culture to its members, conferring them a sense of common identity, like the membership of a team. The desire of any company is to improve ethical performance, and, in order to achieve this, they need to build up, day by day, protection and to introduce it into a daily routine activity.*

*Both managers and employees need guidance on how to act in certain situations that raise ethical questions. The best way to solve these situations is through the existence of a code of ethics that both managers and employees can turn to for guidance at any time and reach the right directions.*

*Completed in July 2010 and entering into force in 2011, the UK Bribery Act is the latest approach to corruption. This Act has been described as the toughest anti-corruption legislation in the world, blaming a behavior that is not acceptable in the global market. With the advent of this new law, many companies were forced to update their codes of ethics in order to meet the new challenges introduced by this law. In this context, our research is based on the study case of the way in which the best performing company in Romania, OMV Petrom, uses in its practice the ethical values that are compulsory at an international level.*

**Keywords:** business ethics, UK Bribery Act, sanctions, code of ethics.

**Jel classification:** F23, K42

## 1. Theoretical Background

In recent decades, ethics has been the subject of many debates between academics and practitioners. The discussions are usually focused on the role of business in society and on the question whether if we could approach business from an ethical point of view. Starting from Friedman's approach (Friedman, M. (1970) *The Social Responsibility of Business Is to Increase Its Profits*, New York Times), during the last decades the concept has evolved; now, managers have understood that by embedding ethics into businesses, they can gain a competitive advantage and promote a sustainable development of the company. The new approach of ethics includes the development and implementation of Codes of Ethics.

### 1.1. Business Ethics

According to the Explanatory Dictionary of Romanian language, ethics is defined as "all rules of good conduct that correspond to an ideology of a particular society or organization."(www.DEX.ro).

Business ethics is a system of principles, values, norms and codes of perception and behaviour, based on a business philosophy that requires a moral obligation by inducing their expression.

"*Business ethics* (ethical economics), a particular form of applied ethics, is a set of rules and moral standards aimed at the agents' economic conduct and activity (business), both individually and collectively" (Iamandi, I.E., (2013) *Etică și responsabilitate socială corporativă în afacerile internaționale*, (www.ai.rei.ase.ro suport curs master), and pursues the activities and success in business.

Business ethics was first embraced by in developed countries, like the U.S. and Western European countries, but in the last decade, the countries of Central and Eastern Europe have become more and more interested in this concept. The reasons for which the countries of Central and Eastern Europe have shown interest in this topic can be both social, because there is a direct relationship between the degree of development of a country and the importance that is given in that state to business ethics, and of economic nature - the competitive pressure induced by the increasing number of multinational corporations that have extended their activity in this regions.

U.S. is the country in which Business Ethics has emerged. U.S. has the largest theoretical and practical experience in the promotion of ethical principles. In the twentieth century, numerous papers and institutions which addressed the importance of implementing ethics in companies have appeared. Currently, over 97% of U.S. companies have their own Code of Ethics.

Business Ethics has been implemented as a subject matter (teaching line) in all business universities, thanks to the fact that some teachers and businessmen considered it necessary to impose American values in their business practice, accepted by the wider community.

Business Ethics appeared in Europe in the mid-80s, both as an academic discipline and as a practical field of interest. In the early 90s, it reached an academic maturity thanks to the emergence of numerous courses, publications and periodicals (*Business Ethics Quarterly* in 1991; *Journal of Business Ethics* - in 1992; *Business Ethics: An European Review* - published quarterly since 1992; *Teaching Business Ethics* - in 1997); associations, centres and professional or educational institutions (examples: Institute of Business ethics - United Kingdom; Ética, Economía y

Dirección, Sucursal Española de European Business Ethics Network – Spain; European Institute of Business Ethics – Holland; Institute for Business Ethics – Switzerland). The first European research centre of Business Ethics appeared at the current St. Gallen University in Switzerland, in 1983.

In November 1987, in Brussels, a milestone was reached in the field of European Business Ethics: the First European conference on Business Ethics took place. The countries that participated in the conference were: Holland, Switzerland, England, Norway, France, West Germany and Belgium. At the end of this conference, the foundation of the European network EBEN (European Business Ethical Network) was proposed, with the purpose of stimulating and promoting discussions on various topics related to business ethics in Europe and, also, for promoting the exchange of information and experiences on European Business Ethics. In only two years, the number of EBEN members has increased impressively, so that at the second European conference - held in Barcelona in September 1989 - EBEN members consisted of representatives of seventeen different countries. (Iamandi, I.E., (2013) *Etică și responsabilitate socială corporativă în afacerile internaționale*, (www.ai.rei.ase.ro suport curs master).

In the year 2000 there were over twenty five European headquarters devoted to studying business ethics and many scientists were dealing with this topic. In 2001, EBEN launched the Forum for Ethics Practitioners Program, the European equivalent of the American Association of Ethics Officers. All over Europe, including the UK, conferences are organized, along with seminars and symposiums, both by academic institutions and by professional organizations or corporations. The objective of this Network (between 44 countries) is to promote the principles of corporate Ethics, of corporate governance and Social Responsibility in the academic community, the EU, the public and private sectors, non-profit organizations and civil societies. (www.eben.com).

## **1.2. Codes of Ethics**

A Code of Ethics is a set of norms and values, which aims to guide the behaviour of members inside the organization, in the relationship between themselves and also in their interaction with society in general. A code of ethics is a tool, a means of transmitting the culture of the organization to its members, giving them a sense of common identity, of being part of a unity. Ethical codes are functional to the extent that they are aligned with the business objectives, however, it should be taken into consideration that the economic performance should not be achieved at any cost. The purpose does not justify the means, thus, the code represents a regulatory instrument, and at the same time a tool for mitigation of reputational risk, associated with the company behaviour (as a “cumulous of individuals” personal behaviours). We consider it is important for an organization to have a code to guide the employees’ behaviour; be it written or not, but it should not be confused with legitimate behaviour.

A Code of Ethics is implemented in order to: define acceptable or unacceptable behaviour, promote high standards of good practice, provide members a benchmark for their own evaluation, and establish the framework of professional and responsible behaviour.

According to Samuel Mercier, the Codes of Ethics have the following objectives (Mercier, S. (1999) *L’etique dans les entreprises*, Editions La Decouverte et Syros, Paris):

- Establishing a moral contract between the organization and its beneficiaries, and also between those who belong to the same organization;
- Protecting the organization from dishonest or opportunistic behaviours;
- Promoting a positive image of the organization;
- Providing a means of regulating the adhesion and the commitment of collaborators;
- Creating a sense of belonging to the group; showing the managers' commitment to principles;
- Obtaining a contractual relationship based on trust and accountability;
- Guiding the behaviours in case ethical dilemmas are encountered.

The effective implementation of any code of ethics depends on the company's human resources, both managers and employees.

## **2. UK Bribery Act as a reference point in Business Ethics**

Corruption undermines democracy, as well as laws and is a serious threat to economic progress for developed countries and especially for emerging economies, and it generally prevents free market access.

Thus, in 2010 in the United Kingdom, after decades of reports and draft laws, appears that which would become the most comprehensive and current legislation in the field of bribery, The Bribery Act. *The* notice was received in April 2010 and came into force on the 1<sup>st</sup> of July 2011. The new law repeals all previous articles regarding corruption and replaces them with articles concerning bribery: offering and receiving bribes to and from foreign officials and the failure of a company to avoid acts of corruption.

The UK Bribery Act attempts to respond to these threats by increasing penalties for bribes, from 7 up to 10 years, but it should also be noted that the objective of the law is not to bring a legal threat to companies. This law seeks to bring a balance, because the legislator is aware of the fact that no corruption prevention system can totally stop bribery.

The law's purpose is to encourage commercial organizations to develop internal procedures and regulations that help to prevent bribery.

It can be considered that this law offers a universal jurisdiction, because it allows the prosecution of companies or natural persons that commit acts that are considered offenses to the United Kingdom, no matter where the offenses occur.

This Act has been described as the toughest anti-corruption legislation in the world, blaming a behaviour that is not acceptable in the global market.

### **2.1. Principles that govern the UK Bribery Act**

- The risk evaluation principle: according to this principle, the risk assessment should be a continuous and dynamic process, not a singular action;
- The top engagement: there must be a 0 tolerance policy for bribery and corruption in the organization's culture, this including business partners too;
- Due diligence assumes an accurate evaluation and a proper risk management before getting involved in a business;
- Policies and procedures should be clear, practical and accessible, and specific guides should be compiled for employees and business partners;
- Effective implementation: anti-bribery measures are to be incorporated in the internal control and recruitment processes; the communication of anticorruption policies should be available in many ways;

- **Monitoring and reviewing:** requires a dynamic and transparent audit and financial controls, as well as internal controls for monitoring ethics and compliance procedures; they must be approved and supported by the Administrative Board and subject to periodic external checks. ([www.worldcompliance.com.Libraries/whitepaper/ukbriberyact](http://www.worldcompliance.com/Libraries/whitepaper/ukbriberyact)).

## **2.2. Penalties provided in the UK Bribery Act**

If a subsidiary of an UK parent company commits an act of corruption in the context of performing services for the company in the UK, it falls under the provisions of the Bribery Act. Foreign companies operating in the UK can be prosecuted for a corruption offense, even if the offense occurs outside the company and the benefit or advantage is intended to accumulate outside the UK. An organization may be guilty of corruption when the act is committed by an employee, agent, subsidiary or a third party ([www.transparency.org.uk](http://www.transparency.org.uk), The 2010 Bribery Act, Section 8), the location being irrelevant.

In Section 11 there is a legislated penalty for an offense under the law: a maximum of 10 years of imprisonment, with an unlimited fine, as well as the potential confiscation of assets involved within the offense (this provision was included in the Act of 2002) and the disqualification of managers under the Company Directors Disqualification Act. (1986). The law has an almost universal jurisdiction to allow prosecution of an individual or company with ties by the United Kingdom, no matter where the offense has occurred.

The first penalty imposed under the new legislation took place in 2012. The company Abbot Group Limited has paid a fine of £ 5.6 million, after the company admitted that it had benefited from corrupt practices in 2007. One of the foreign subsidiaries paid bribes in connection with a contract with a foreign company for oil and gas. The contract ended in 2006, and the offense occurred in 2007. The amount of the fine was equal to the profit made by the company thanks to the transaction, £5.6 million. (<http://www.crownoffice.gov.uk>).

## **3. Monitoring Ethics aspects at an international level**

The fact that large companies promote the principles of sustainable development more and more, as a vector of their business success, is nothing new. Such an approach assumes an increase of responsibilities for the promotion of Business Ethics principles and values. Nevertheless, besides these responsibilities that belong to the companies, the instruments that can be used by authorities for monitoring the implementation of Business Ethics principles and for punishing any deviations, are strengthened.

On this basis, any deviation from the principles and ethical values in business are severely punished by the national authorities in order to provide a healthy environment for doing business.

For exemplification, we will show the largest cases of punished acts of corruption, in the last five years, at an international level.

**Table 1:** Fines for the biggest acts of corruption

Nr. Cr.	Company	Country	Fee Amount(mil. dollars)	Year
1.	Siemens	Germany	1600	2008
2.	KBR/Halliburton	USA	579	2009
3.	BAE Systems	USA	448	2010
4.	Snamprogetti	Holland	240	2010
5.	Technip SA	France	240	2010
6.	JGC Corporation	Japan	219	2011
7.	Daimler AG	Germany	195	2010
8.	Alcatel-Lucent	France	137	2011
9.	Panalpina	Switzerland	76	2010
10.	Johnson & Johnson	USA	70	2011
Total			3804	

Source: data gathered from [www.thefiscaltimes.com](http://www.thefiscaltimes.com)

The main aspects that emerge from the situation presented above are:

- The volume of fines given to international large companies has risen very much, reaching figures of billions of Dollars;
- All of these fines were given by American authorities
- The biggest fine was given to the German company Siemens, fact that initiated/ triggered an ample process of defining the Compliance Program at the company's level.

#### 4. Business ethics principles in Romanian companies

##### 4.1 Romanian legal framework

In Romania, the bribery legislation is set out in The Penal Code, Article 254, paragraph 1: "taking bribes" in the legislator's opinion, is: "The official's act of demanding or receiving money or other benefits, directly or indirectly, the claiming or receiving money or of benefits that are not his to claim, in order to perform, not to perform or delay performance of an act concerning of his office duties or in order to do an act contrary to these duties, shall be punished with imprisonment from 3 to 12 years and interdiction of certain rights". "Anyone who commits the act presented in paragraph 1, an official with control duties, shall be punished with imprisonment from 3 to 15 years and interdiction of certain rights. The money, valuables or any other goods that have been gained by taking bribery are to be confiscated and, if they are not found, the offender is obliged to pay their equivalent in money". (<http://legeaz.net/cod-penal-actualizat-2011/art-254-cpen>).

In Article 255 the offense of bribing is defined as "promising, offering or giving money or other benefits", in the ways and for purposes described in Article 254, shall be punished with imprisonment from 6 months to 5 years. The act is provided in the preceding paragraph which is not an offense when the briber was forced by any means by the one who took bribes. (<http://legeaz.net/cod-penal-actualizat-2011/art-255-cpen>).

The Romanian legislator approaches in The Penal Code also the offense of work or related to work, that is "acceptance of undue advantages" (Article 256) and "trading

in influence" (of Article 257). The first offense is punishable by imprisonment, from 6 months up to 5 years, and in the case presented in Article 257, the punishment is imprisonment from 2 to 10 years, and in both cases the money, valuables or other property or benefits gained, shall be confiscated.

When comparing the two laws, the UK Bribery Act and Articles of Romanian Penal Code, we can conclude that both legislations refer to the offense of giving and taking bribes, as well as the maximum penalty for these offenses being, in both cases, 10 years. Analysing both laws in terms of territoriality; we find that the UK law takes effect throughout its territory and also beyond its state borders. Both the Romanian and the British law refer to bribery in private and public activity. The extraterritoriality principle assumes that companies must align their programs and anti-bribery policies to the ones of the companies with which they have business relationships.

#### 4.2 Case studies on companies' practices in Romania

Knowing the Romanian legislation in force and also the international law, in the first phase of the research, we intended to evaluate the way in which the ten most important Romanian companies implemented or not the Code of Business Ethics. We analysed the companies with foreign capital, domestic capital as well as the top ten in terms of turnover in 2012.

The results of this evaluation are given in the table below:

**Table 2:** List of the biggest companies operating in Romania, having or not a Code of Ethics

Crt. no.	Companies with foreign capital	Code of ethics	Companies with Romanian capital	Code of ethics
1.	OMV Petrom	Yes	Romgaz	No
2.	Orange Romania	Yes	Nuclearelectrica	No
3.	Vodafone	Yes	Hidroelectrica	No
4.	BRD	Yes	RCS&RDS	No
5.	BCR	Yes	Aeroporturi București	No
6.	Automobile Dacia	Yes	Interagro	No
7.	Romtelecom	Yes	Electrocentrale București	No
8.	Enel Distribuție Muntenia	Yes	Transilvania Bank	Yes
9.	Kaufland	No	Dedeman	No
10.	E.On Gaz Distribuție	No	Mediplus Exim	No

Source: made by authors based on data from INS and companies' websites.

It can be stated that the companies operating in Romania are becoming more and more responsible when it comes to promote a sustainable development, based on Business Ethics principles and values. We are referring mostly to the companies which have a foreign capital that use a Code of Business Ethics at a rate of 80%. It feels, however, that such ethical values should be promoted by Romanian companies as well (only 10% of such considered companies have this type of an instrument).

In the second phase of the research, we have focused on evaluating the way in which the biggest company in Romania, OMV Petrom, approaches Business Ethics.

For this purpose, we started from the company's undertaken responsibility regarding sustainable development and the promotion of the three main pillars of this concept, that is: economic development, care for the environment and the responsibility for the community in which the company conducts its activity. The study made has shown that this company assumed the responsibility of promoting the Business Ethics values and principles in its relation with its employees, as well as with its stakeholders.

Therefore, implementing a Code of Business Ethics, which is conceived as an instrument of assuring a durable basis for development, is to be noted.

In OMV Petrom's case, the company's management has assumed the principle of zero tolerance for bribery, fraud, theft and other means of corruption in which employees are fostered to admit, prevent and report any abnormality which is related to these acts of corruption. OMV Petrom's Code of Ethics regulates issues like: conflicts of interest, bribery and facilitation payments, offered / received gifts and gratuities regime, competition and anti-trust issues.

It is important to mention that at company's level, it was set-up by a series of instruments, capable of sustaining the efficient implementation of Business Ethics principles, for example: the approval methodology and competencies of gifts, their registries, the provisions' application guideline related to gifts, conflicts of interests, competition practices, etc.

Furthermore, in order to be efficient in implementing the Business Ethics aspect a compliance structure was created for the company, in order to assure, on one hand, the promotion of business ethics culture within the organization and, on the other hand, the relationships with the company's employees and its stakeholders. In order to achieve this, there have been implemented new ways of communication, dedicated to this purpose. In order to increase efficiency against any form of corruption, the company has developed a compliance programme, which intends to identify and mitigate the risks, as well as to avoid fines like the ones mentioned before, for the other companies. It can be concluded, thus, that if there is responsibility, the legal framework and mentality of Romania are in no way a major obstacle for implementing the principles of Business Ethics within companies' activity.

## **Conclusions**

Based on the theoretical and practical aspects included in this paper, a lot of relevant conclusions can be drawn, regarding the implementation of the principles and values of Codes of Business Ethics. At the same time, the growth of companies' responsibilities for sustainable development imposes without doubt the need to combine imminent objectives with those of environmental protection and of developing the relationships with the communities in which they carry out their actions. For this, it is necessary to adopt Codes of Business Ethics which lead to sustainable solutions for business situations the companies are confronted with.

The research has highlighted a few important conclusions, as follows:

- The states' efforts must be enhanced in order to provide a more and more efficient legislation against companies' acts of corruption. Hence, the laws applicable are becoming more strict;
- The increasingly active involvement of authorities in monitoring the existence and implementation of Business Ethics principles in companies;

- The continuous growth of companies' interest and responsibilities for the promotion of clean business practices, which eliminate any doubt regarding ethics;
- The increase of authorities' actions and the elimination of any deviations from Business Ethics norms. The fines given by them in this purpose affect the most important international companies and their amount has reached the level of billions of dollars;
- The discrepancy which is still maintained on the Romanian market, between the Business Ethics practices of companies that have a foreign capital and the companies that have a domestic capital. The first category implements the Codes of Business Ethics at a rate of 80%, while the second one applies such practices only at a rate of 10%;
- The case study based on the practice of OMV Petrom regarding Business Ethics highlights the fact that a responsible company can successfully operate on the Romanian market, given the conditions in which it adopts and implements a Code of Business Ethics, which guarantees the support of sustainable development.

The Romanian legal framework, as well as our mentalities cannot be used as an excuse by responsible companies to lack the promotion of the principles and values of Business Ethics. The study case we completed for OMV Petrom's situation fully demonstrates this conclusion

[andreea.fora@gmail.com](mailto:andreea.fora@gmail.com)

**Abstract:** *The abuse of dominant position along with cartel, merger and state aid are practices restricting competition strictly regulated at EU level. These practices can have a disastrous effect on the internal market harming both competition especially consumers. These practices can have a disastrous effect on the domestic market harming both competition and especially consumers. This paper aims to analyze how the abuse of a dominant position is regulated in the European Union. The research methodology used is the study of literature, analysis of legislation, case study, and the collection and interpretation of statistical data. The Competition Law at European level is harmonized among European Union member states. The competition authorities of the EU Member States work together to detect and sanction the practice that is restrictive for competition. Improving legislation that regulates the abuse of dominant position has been an ongoing concern of competition authorities, which is why the EU currently enjoys a very well established procedure. The procedure governing the abuse of dominant position consists of a series of steps that must be taken gradually to have the desired result, i.e. restoring fair competition on a given market. The case study presented in this paper is indicative and shows very clearly the next steps for referral to an abuse of dominant position, with special reference to the outcome arising when applying the procedure correctly. The analysis of statistical data regarding the number of investigations opened and the number of decisions made by competition authorities on abuse of dominant position is relevant, outlining the evolution of the work performed by competition authorities. Throughout the period of ten years analyzed (January 2004 - February 2013) there were 1583 cases of violation of antitrust laws at European level. The percentage of investigations opened by the competition authorities of the Member States is 86%, much higher than the number of investigations opened by the European Commission (14%). Both the activity of the competition authorities and especially the importance of competition policy as well as the guardian position for consumer protection assumed by the Competition Council in each Member State of the European Union have to be underlined.*

**Keywords:** *abuse of dominant position; competition policy; European legislation; procedure; case study*

**JEL classification:** K21; L41

## **1. Regulations on abuse of a dominant position**

The abuse of dominant position was regulated at EU level by Article 82 of the *EC Treaty*, being currently replaced by Article 102 of the *Treaty on the Functioning of the European Union*. In Romania the abuse of dominant position is regulated by Article 6 of Law No. 21 of 2006. The Competition Law in Romania is harmonized with the European legislation.

The competition policy is closely monitored at EU level as anticompetitive practices can have a devastating effect on the domestic market. The dominant position of a company is not prohibited, but the abuse of a dominant position is considered illegal. Article 102 of the *Treaty on the Functioning of the European Union* prohibits the abuse of a dominant position on a market by one or more companies. According to present legislation, abuse of dominant position concerns: the price fixing, limiting production and marketing of products as well as limiting technical progress at the expense of consumers; imposing dissimilar conditions to equivalent transactions among trading partners, conditioning the conclusion of contracts by the existence of some additional benefits (Consolidated versions of the Treaty on the Functioning of the European Union, 2010).

The company or companies that are in a dominant position have a responsibility not to distort competition. If only one company is on a dominant position, we have to do with a unique dominant position, whereas if more undertakings are dominant we talk of collective dominance. Competition authorities consider it necessary to intervene when a company commits an abuse of a dominant position because it not only protects consumers but also competitors. At European level the abuse of a dominant position is defined as the situation where an enterprise has that much economic power that can act independently of both competitors, trading partners, and especially of consumers.

The analysis of the relevant market plays an important role for antitrust practices. Competition authorities are extremely thorough when settling both the relevant product market and the relevant geographic market. In order to clearly define the relevant geographic market from the relevant product market, the competition authorities have to collect a series of information. This information can be already in the possession of authorities or they may be required to companies. Based on the information gathered and applying tests, competition authorities are able to accurately determine the relevant product market and relevant geographic market.

The first issue considered by the European Commission is the market share held by the company in a relevant market. A market share exceeding 40% in the relevant market is a warning; nevertheless the period in which the respective market share is being held should not be neglected. Additionally, the impossibility of some competitors to enter and expand in that market is another signal to the competition authorities. The company holding a dominant position may impede competition to enter and expand in the relevant market through a variety of means: the existence of some contracts with suppliers and customers for very long periods of time, the existence of a very well organised distribution network, privileged access to the raw materials required and the benefits from the existence of economies of scale and possession of the latest technology.

Authorities in the field examine the power of pressure of clients on a certain company in a dominant position, because even if the company has a high market share, but its customers put a pressure that is able to influence the company

behaviour, then the abuse of dominant position of that company is unlikely. In addition to the factors mentioned above, when analysing the abuse of dominant position, the Commission considers a number of specific factors. These factors refer to: low selling prices of products, imposing certain exclusive supply contracts on customers, offering customers conditional discounts on the volume of products or services purchased, tying or bundling of products sold to customers and unjustified refusal to work with new customers.

When facing a possible abuse of a dominant position, European Commission considers both the general factors and the specific ones listed above, comparing them with the normal situation that should exist in a competitive market. The ultimate objective of the competition authorities, in terms of restricting the abuse of a dominant position is to protect competition and consumers in particular, by enabling the latter to choose from a variety of products in the quantities they want and benefiting of the optimal price performance ratio.

## **2. Overview on the Conduct of Proceedings for Abuse of Dominant Position**

At European level the way of conducting proceedings for abuse of dominant position is regulated in the smallest details. In case of abuse of dominant position investigations are opened by the European Commission or the Member States' competition authorities *ex-officio* or following complaints lodged by other companies or individuals. Competition authorities of the EU Member States work closely *with* the European Commission throughout the investigation.

Before opening the investigation, there is an initial assessment. In the initial assessment the information is analyzed and, based on the knowledge available, there are two decisions that can be made: suspend the investigation if the complaint is not justified, because they do not infringe Article 102 or start further investigations and requests for further information. Also, at this stage, the authority in charge with the case is being set. The case can be assigned to the European Commission or the competition authority of a Member State of the European Union. If, following the initial assessment, further investigations is considered necessary, the decision on the opening of proceedings will be issued. This decision is communicated to stakeholders and later published on the website of the Directorate General for Competition, together with a press release.

After issuing the decision to open the proceedings, the competition authorities may require certain information. Requesting information does not only refer to the involved companies, but also to other persons or companies able to provide information relevant to the case. The requested information has a time limit enabling stakeholders to respond in a timely manner.

The communication between the competition authority and the investigated company can be carried out in one of the language acknowledged in the European Union, according to the preferences of the company performing the investigation.

During the investigation stage, there is a series of meetings aimed to help the investigation. During these review meetings, the parties may express their views. Also, during the investigation stage unannounced inspections at the headquarters of the companies involved can take place. Throughout the entire investigation the information is confidential.

The investigation stage may be concluded as follows: the competition authority considers that the allegations are substantiated and the investigation should continue; the parties propose a number of commitments aimed at ending the abuse

of dominant position; the Competition Authority stops the investigation as complaints are unfounded.

In case the investigation continues, stakeholders are heard. Throughout the oral hearings the companies have the opportunity to answer all objections made by the competition authority. This stage may have two results: the competition authority decides that Article 102 of the Treaty on the Functioning of the European Union has been violated, or they may decide to close the case on the grounds that the allegations were unfounded. Before issuing its decision of violation of Article 102, the Advisory Committee is also consulted. By means of this decision the abuse of a dominant position is prohibited.

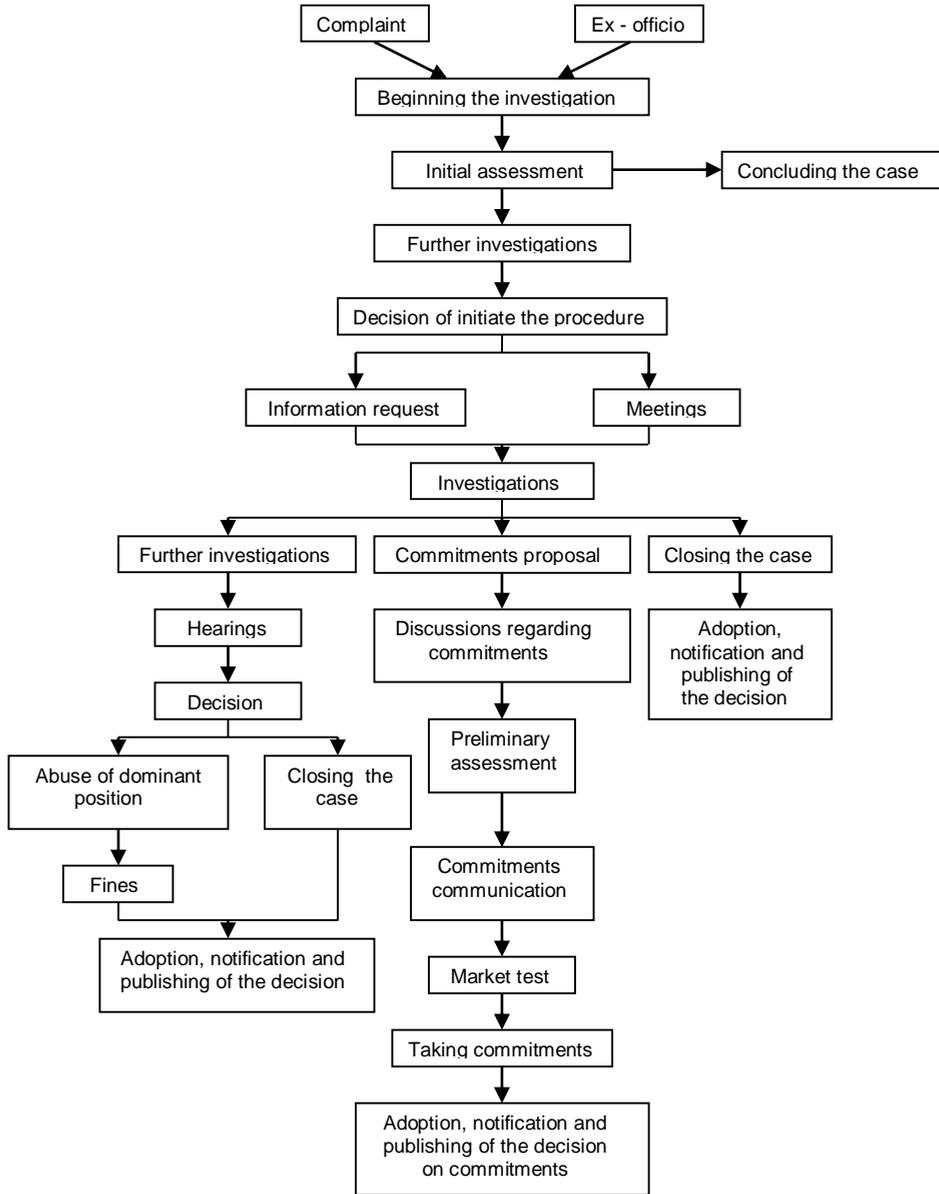

If the abuse of dominance is found, the competition authority may impose a fine of an amount not exceeding 10% of the turnover of the previous financial year. Fines of 1% of the turnover of the previous financial year may apply to companies that do not wish to provide the requested information or provide incomplete information. Also, for each day of delay of information, the competent authority may impose a fine of 5% of the average daily turnover figure of the previous fiscal year (EU Competition Law Rules Applicable to Antitrust Enforcement, 2011).

If the company involved proposes a series of voluntary commitments to restore competition and to stop abuse of dominance, the competition authority should consider the proposals. Thus, the discussions regarding the commitments are initiated, followed by a preliminary evaluation. In the preliminary evaluation stage there is a series of meetings between representatives of the authorities and stakeholders.

This assessment can be completed by formulating certain commitments by the company involved. These commitments must be disclosed and made within one month from the completion of the preliminary assessment. Before these commitments become binding, the competition authority carries out a market test. Depending on the outcome of the market research those commitments become binding or they are improved, in which case the market test should be repeated. After the market testing, the opinion of the Advisory Committee is required, and subsequently the decision on commitments is issued.

The decisions made by the Commission or the competition authorities of the Member States are made public to the interested parties as soon as possible. The decision is made public through a press release and the summary of the decision is published in all official languages of the European Union in the Official Journal of the European Union. The complete decision and the final reports are published on the website of the competence Authorities.

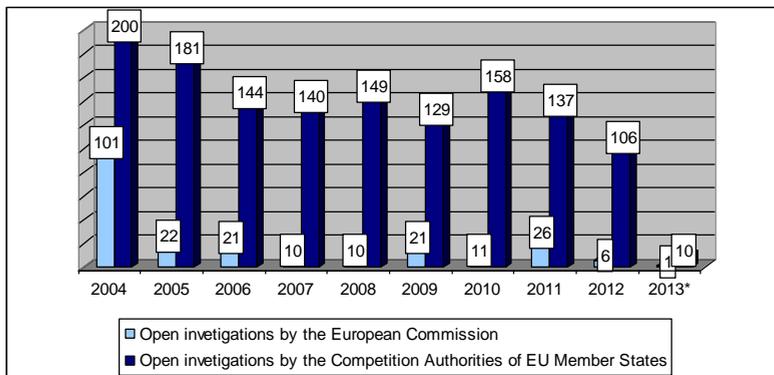

The conduct of the proceedings for abuse of dominant position may be summarized as in the figure below.

**Figure 1: The conduct of the proceedings for abuse of dominant position**  
 Source: made by the author based on data from Commission notice on best practices for the conduct of proceedings concerning Articles 101 and 102 TFEU

### 3. The Evolution of the Investigations and Decisions on Abuse of Dominant Position

In the European Union, between January 2004 and February 2013, a number of 1583 investigations of antitrust cases were opened (violation of Article 101 and Article 102).

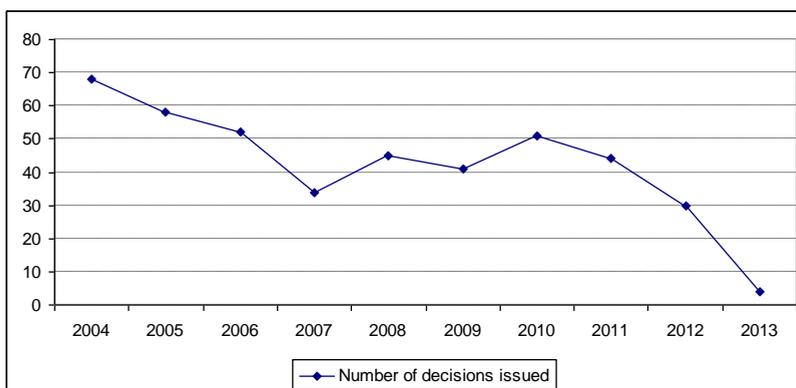

**Chart 1:** Developments in EU antitrust investigations in the period January 2004 - February 2013

Source: made by the author based on data from <http://ec.europa.eu/competition/ecn/statistics.html>

In Chart 1 we can notice the evolution of antitrust investigations opened by both the European Commission and the competition authorities of the Member States. The percentage of antitrust investigations opened by the competition authorities of the Member States (86%) is much higher than the share of the investigations opened by the European Commission (14%).

Most investigations were opened in 2004: 200 initiated by the competition authorities of the Member States, the European Commission initiated 101 respectively.

**Chart 2:** Developments in EU antitrust decisions in the period January 2004 - February 2013

Source: made by the author based on data from <http://ec.europa.eu/competition/ecn/statistics.html>

Analyzing Chart 2 we notice the evolution of antitrust decisions issued in the European Union, between January 2004 and February 2013. Most antitrust decisions were issued in 2004 and the fewest in 2012 (except for 2013 for which data are known only until February).

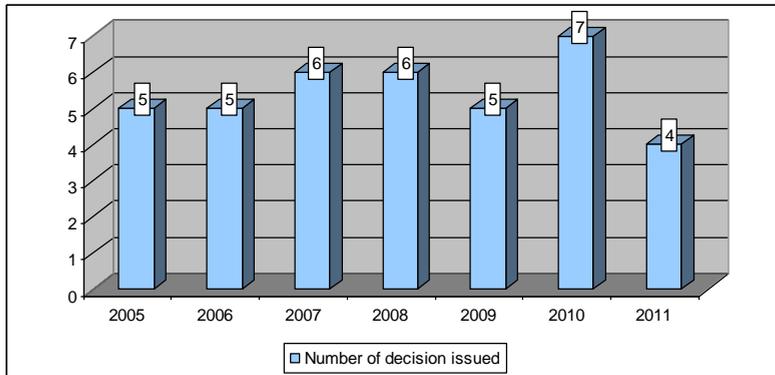

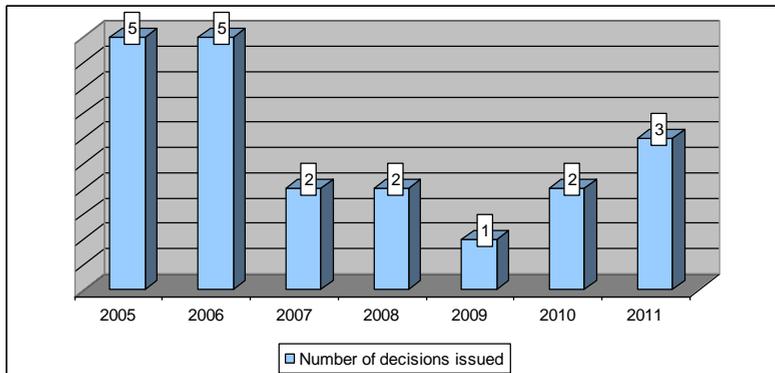

Chart 3: The evolution of abuse of dominance decision issued by the European Commission between 2005 and 2011. Source: made by the author based on data taken from the Annual reports competition

Chart 3 shows the evolution of decisions regarding the abuse of dominance issued by the European Commission between 2005 and 2011. The number of decisions made annually is approximately constant, the peak being recorded in 2010 (7 decisions).

**Chart 4: The progress decisions on the abuse of dominant position issued by the Competition Council of Romania between 2005 and 2011**  
Source: made by the author based on data taken from the Annual reports of the Competition Council of Romania

Chart 4 shows the evolution of decisions on abuse of dominant position in Romania, between 2005 and 2011. Most decisions were issued in 2005 and 2006 (5 decisions), and in 2009 a single

decision regarding abuse of dominant position was issued.

#### 4. Case Study: ENI

ENI is a company operating in the energy sector in Italy. ENI is a state-controlled enterprise whose activity is related to generation, transmission and supply of natural gas in Italy (Case COMP/39.315 – ENI, 2010).

The European Commission started investigations on possible abuse of a dominant position regarding ENI ex-officio. In May of 2006 there were surprise inspections at ENI. The role of these inspections was to gather as much information as necessary for the initial assessment stage. In 2007 the European Commission issued the decision to initiate the procedure regarding the infringement of Article 102 of the Treaty on the Functioning of the European Union. The investigations continued until March of 2009. Throughout these investigations a series of information have been requested to ENI. ENI responded promptly to all inquiries.

The report of the European Commission of March 2009 found the company guilty of violating Article 102 that is of abuse of a dominant position. The report stated that Italy was dependent on imported gas and ENI controlled all gas pipelines across the country. In addition the company dealt with the distribution of these gases with long-term contracts with both industrial and small consumers. The report concluded that ENI had committed an abuse of a dominant position in terms of infrastructure control of the system for importing gas throughout Italy. The European Commission made its findings known to ENI.

ENI was dissatisfied with the conclusions of the report, but was willing to cooperate further with the European Commission, participating in hearings held thereafter.

Following these hearings ENI proposed a number of commitments designed to eliminate the abuse of dominant position. There have been a number of discussions between the prosecution and the European Commission on those commitments, and then they underwent a preliminary assessment. In February 2010 ENI communicated its commitments. These commitments were published, and the Commission invited interested parties to express their views. Although the Commission received some complaints about the commitments proposed by ENI, it considered that the complaints were not justified. After the market test, the commitments proved to be viable, so that the ENI was forced to take the proposed commitments. The commitments related mainly to the disposal of shares held in the infrastructure for gas import system and to the company's obligation of not concluding very long term contracts on natural gas distribution. The European Commission concluded that the above-mentioned commitments were sufficient to restore fair competition on the gas market in Italy, removing the threat of preventing other European competitors from entering the respective market.

In September 2010, when the Advisory Committee has already been consulted the procedure ended with the adoption, notification and publication of the decision on commitments. Since then the commitments have become binding for ENI. The decision was made public later in a press release. The summary of the decision was published in the Official Journal of the European Union in all official EU languages; the full –length decision together with the opinion of the Advisory Committee and the final report were published on the website of the Directorate General for Competition.

## 5. Conclusions

At European level competition is one of the most important policies because the integrity of the domestic market can be granted only under very strict competition. The abuse of dominant position is one of the restrictive competition practices. The dominant position of a company is not prohibited; it is only the abuse of dominant position that is punished.

The abuse of dominant position is contrary to the competition rules as it harms both competition and consumers equally. Accepting an abuse of dominant position on a market would gradually eliminate competitors, and the very existence of some poor-quality goods or services on the market, while maintaining high prices.

At EU level a constant attention was noticeable regarding the improvement of the legislation that regulates the restriction of the abuse of a dominant position over years. The procedure for the detection of abuse of a dominant position is well established, the steps are very clear.

Evidence of this concern is reflected by the evolution of the investigations and decisions on the abuse of a dominant position at European level. Within ten years (January 2004 - February 2013) no less than 1583 investigations of violations of Article 101 and 102 of the Treaty on the Functioning of the European Union were opened.

Thus we can assert that competition authorities have been, are and will be the guardian of consumers.

The analysis of the way a case of abuse of dominant position in Romania is instrumented as well as the analysis of the other restrictive competition practices shall constitute the topic of further research.

# MEDICAL BRAIN DRAIN - A THEORETICAL APPROACH

**Boncea Irina**

*Faculty of International Business and Economics, Bucharest University of Economic Studies, Bucharest, Romania  
irinaboncea@gmail.com*

**Abstract:** *Medical brain drain is defined as the migration of health personnel from developing countries to developed countries and between industrialized nations in search for better opportunities. This phenomenon became a global growing concern due to its impact on both the donor and the destination countries. This article aims to present the main theoretical contributions starting from 1950 until today and the historical evolution, in the attempt of correlating the particular case of medical brain drain with the theory and evolution of the brain drain in general. This article raises questions and offers answers, identifies the main issues and looks for possible solutions in order to reduce the emigration of medical doctors. Factors of influence include push (low level of income, poor working conditions, the absence of job openings and social recognition, oppressive political climate) and pull (better remuneration and working conditions, prospects for career development, job satisfaction, security) factors. Developing countries are confronting with the loss of their most valuable intellectuals and the investment in their education, at the benefit of developed nations. An ethical debate arises as the disparities between countries increases, industrialized nations filling in the gaps in health systems with professionals from countries already facing shortages. However, recent literature emphasizes the possibility of a “beneficial brain drain” through education incentives offered by the emigration prospects. Other sources of “brain gain” for donor country are the remittances, the scientific networks and return migration. Measures to stem the medical brain drain involve the common effort and collaboration between developing and developed countries and international organizations. Measures adopted by donor countries include higher salaries, better working conditions, security, career opportunities, incentives to stimulate return migration. Destination countries could fight against the exodus of physicians through self-sufficiency, financial compensations paid for the skilled workforce coming from developing countries and agreements forbidding the recruitment of health professionals from countries already suffering of scarce resources. International organizations’ contribution includes collaboration and actions oriented towards the adoption of an ethical guideline. As the medical brain drain is a global concern, its contraction requires global solutions.*

**Keywords:** *brain drain, medical brain drain, migration, health system*

**JEL classification:** *F22, J21, J24, O15*

## **1. Introduction**

Medical brain drain is defined as the migration of health personnel in search of better opportunities (Dodani and LaPorte, 2005). Although the majority of definitions mention as direction of emigration the one from developing to developed countries, the first to confront with this phenomenon were the developed nations. A proper definition should be: the migration of physicians from developing to developed

countries and between industrialized nations (Wright, Flis and Gupta, 2008). An interesting definition (Muula, 2005) include the loss of health workers (named hard brain drain) and the unavailability of research results to users, in the particular case of Africa (soft brain drain).

Starting with a literature review, this article has two major objectives. Firstly, the article identifies the main theoretical contributions and historical evolution of two phenomena: brain drain and medical brain drain, in the attempt of correlating and emphasizing the similarities. Secondly, the article seeks to raise questions and offer answers, identify main issues and propose solutions for the reduction of medical doctors' emigration from developing to developed countries.

## **2. Literature review**

The four decades of economic research of the brain drain evolution resulted in the highlighting of three main waves (Docquier and Rapoport, 2011). The first wave of economics papers (Grubel and Scott, 1966, Johnson, 1967, Berry and Soligo, 1969) pointed out that the impact of the brain drain on source countries is a neutral one, to some extent even benefic (remittances and positive feedback), the world economy gaining from the free migration (Docquier and Rapoport, 2011).

The second wave (Bhagwati and Hamada, 1974, McCulloch and Yellen, 1977, Miyagiwa, 1991, Haque and Kim, 1995) disclosed the negative impact of the brain drain on the country of origin (unemployment, reduction of economic growth rate, distortions on labour markets, decreased human capital accumulation) and the emphasis of disparities between countries (Docquier and Rapoport, 2011). A solution proposed was the financial compensation ("Bhagwati Tax") offered by the developed nations to the developing ones for their loss of skilled workforce.

The third wave of interest, named the new economics of brain drain (1990s), accepted both the detrimental and beneficial effects on the country of origin. An important contribution represented the empirical studies (Carrington and Detragiache, 1998, Docquier and Marfouk, 2005, Dumont and Lemaître, 2005, Beine et al., 2006), which offered a better understanding of this phenomenon's magnitude (Docquier and Rapoport, 2011).

The medical brain drain and its impact on developing countries attracted interest and reactions amidst research community. Studies tackling the health domain are scarce and little has been written about the historical origins, but to some extent, the three stages of evolution can be identified.

Early literature in the medical brain drain domain consisted in American and British studies pointing out the impact in the "first world" countries (McKay, 1969, Abel-Smith and Gales, 1964, in Wright, Flis and Gupta, 2008) and even more, the benefits offered to developing countries in terms of experience and access to advanced technology, gained by their emigrants (Rashi Fein, 1967, Margulies and Bloch, 1969, in Wright, Flis and Gupta, 2008).

The next wave of studies (J. Van Hoek, 1970, Committee on the International Migration of Talent's study, 1970, in Wright, Flis and Gupta, 2008) reflected the lack of accurate statistical data as the main limit in the process of quantifying the impact of health professionals' migration on developing countries and pointed out the detrimental effects over the donors. The three monographs published between 1971 and 1977, by Oscar Gish, investigated the economic impact on developing countries (Wright, Flis and Gupta, 2008).

Based on these studies, WHO published several reports (in 1973, 1975, 1976, 1978, 1979) emphasizing the complex nature of the international migration of health workforce, where the poorest countries were the losers (Wright, Flis and Gupta, 2008).

Recent literature consists of both theoretical and cross-country empirical studies, underlining the positive and negative effects of medical brain drain mostly on the country of origin, the ethics of the phenomenon and also the global measures that should be taken in order to find a solution for a global growing concern.

The possibility of a “beneficial brain drain” (Beine, Docquier and Rapoport, 2001) through education incentives was also analyzed. Kangasniemi et al. (2007) applied a survey to the Indian doctors working in United Kingdom and found relatively weak links between the migration possibilities and the education decisions (only a percent of 28%). However, the necessary condition for a brain gain is that the proportion of students reacting to emigration prospects exceeds the actual emigration rate. Moreover, in another study, Defoort, 2009 (in Docquier and Rapoport, 2009) identified an optimal brain drain rate of 9 percent, concluding that the number of African countries affected by the medical brain drain (20) is inferior to the number of countries that will report a gain (30) from an increase in medical emigration rate (Docquier and Rapoport, 2009).

### **3. Historical evolution**

Brain drain phenomenon attracted the interest of researchers and provoked controversy starting from its origins (in 1950s) until present. Although the highly skilled migration has its roots in prehistoric times, significantly outflows were reported from the third decade of the 20<sup>th</sup> century (the inter-war period being defined as a forced emigration from Europe to the United States – German intellectuals requesting asylum) (Brandi, 2004).

The period of time from 1946 to 1960 was characterized by an attractive immigration policy implemented by the United States and a context of economic privation affecting most of the European countries. As a consequence, between 1956 and 1961, Britain and Germany supplied USA with scientists: 28.23%, respectively 22.59% of the total emigrants (scientists). Both countries were suffering damages after the War and were incapable of absorbing the surplus of intellectuals produced by their first-class universities, whose emigration was inevitable (Brandi, 2004). Canada and Australia represented also destination countries for skilled emigrants.

The term “brain drain” was mentioned for the first time in Royal Society of London’s Report (1963) correlated with the ruinous effects of highly skilled workforce emigration on Britain’s economy (Brandi, 2004). Measures were introduced by governments in donor countries in order to diminish the exodus, felt by the US in a drastic decline of British and German immigrants.

The medical brain drain had a similar evolution. The necessity of filling the gaps in the health system with foreign workforce led to a number of 12 000 new foreign medical graduates registered in the United States by 1973.

British medical graduates and physicians crossed the Atlantic in order to find new opportunities in United States or Canada, or, even more, in Australia and New Zealand (Wright, Flis and Gupta, 2008). The gaps in the health system were filled by an inflow of foreign doctors – in 1966, a number of 8785 physicians from developing world were working in Britain, 70% coming from India (Wright, Flis and Gupta, 2008).

The period from 1970 to 1980 was defined by new migration flows. United States continued its policy of attracting students and intellectuals, but developing countries became the main source. Due to a lack of academic institutions in their country of origin, the outflows consisted in an increased number of students from the former colonies (Britain and France being the most common destinations) or Asian countries. The US maintained its top position as a recipient country, but other industrialized countries began to attract skilled emigrants – United Kingdom, Canada, Australia, Germany, France (Brandi, 2004). The evolution of the medical brain drain was similar during this period of time.

Between 1960s and 1970s, industrialized countries confronted with personnel shortages in the health sector. The need of recruiting outside its borders came naturally and the ex-colonies represented the main source. The setting of medical universities in the new territories by the great colonizers and the good command of English language, combined with the desire for a better life and the insufficient salaries and inadequate equipment conducted to the emigration of medical doctors to the developed world (Arnold, 2011:351).

The estimations regarding the loss of physicians from developing to developed countries was of 70 000 in 1972 alone (Wright, Flis and Gupta, 2008).

After reaching a peak in 1966-1975, physician migration reduced its level, as industrialized nations oriented through the self-production of a sufficient number of medical doctors (Wright, Flis and Gupta, 2008).

In Europe, the free movement of labour force established by the Treaty of Schengen resulted in a rise in the number of skilled migrants, but, due to the lack of proper monitor, the consequences are difficult to be interpreted. The result was, mainly, a “brain exchange” (Straubhaar, 2000:20). The phenomenon is common to the health sector – 60% of Switzerland’s international medical graduates are from Germany, as do 33% of Norway’s (Mullan, 2005:1816).

After 1990s, the globalization phenomenon and the development of ITC industry created the premise for a global competition between industrialized nations (USA, Canada, Australia, France, Britain) in attracting the highly skilled. After the dissolution of the Eastern Bloc, the former communist countries offered a new source of skilled emigrants – between 1990 and 1995, Russia lost 120000 intellectuals (Brandi, 2004).

Developed nations attract physicians from developing countries but also draw on each other: Britain physicians represent the largest group of international medical graduates in Canada and Australia, and Canadian physicians are placed on the fifth position in the top of medical immigrants in United States. This is the case of a “brain circulation”, where the net beneficiaries are US and Australia and the net donors are UK and Canada (Mullan, 2005:1814).

A recent study of physician brain drain analyzing the emigration factor (reflecting the level of emigration of physicians from each source country to the 4 recipient countries – US, UK, Canada and Australia) concluded that lower income countries contribute with 40% of the international medical graduates in Australia and with 75.2% in United Kingdom (Mullan, 2005:1813). India is the country that sends the most physicians to recipient countries, followed by Philippines and Pakistan (Mullan, 2005:1814).

African continent is the most affected by the medical brain drain phenomenon. Also, it is particularly severe in Sub Saharan Africa, South Asia, East Asia and Latin America. The most affected countries are Grenada, Dominica, Saint Lucia, Ireland, Liberia, Jamaica and Fiji (Docquier and Rapoport, 2009). Dominica has an

emigration rate of health professionals of 98.1% (2 doctors out of 100 educated will remain in the country), followed by Grenada – 97.9% and Santa Lucia – 69.8% (Docquier and Schiff, 2009).

Importers of medical personnel are Australia, Canada, France, Belgium, UK and US. Donor countries could be classified into surplus countries voluntarily sending medical workers abroad (Cuba, India, Egypt and Philippines) and shortage countries (Africa, the Caribbean and Asia) (Rutten, 2009).

The emigration rate of doctors is highly correlated with the emigration rate of highly skilled in general, the impact on the socio-economic development being harsher for the first category (OECD, 2007).

The ethics of this phenomenon is questionable, as the disparities between developed and developing countries are growing constantly. Developed nations supply their gaps with skilled workforce from developing countries, the latter confronting with scarce human resources and the loss of their investments in creating highly skilled individuals.

The main issue related to the medical brain drain phenomenon is the accuracy of statistics existent. Developing countries don't hold accurate statistics concerning the emigration of medical doctors, which is a hindrance in monitoring and assessing the impact. Usually, the empirical studies are based on data available in destination countries or in international databases (WHO, World Bank, etc). Another limit is the different definition offered by literature, which leads to difficulties in comparing the values between countries: Clemens and Peterson (2006) use the country of birth for defining medical emigrants, whilst Docquier and Bhargava (2006) use the country of training (Docquier and Rapoport, 2009).

#### **4. Medical brain drain and developing countries**

The majority of skilled emigrants in health sector come from developing countries, fact that attracted controversy at international level regarding the impact over the health system and economic growth of donor countries. A combination of economic, social and personal factors contributes to the decision of leaving the country (Dodani and LaPorte, 2005).

*What factors influence the medical brain drain?* Some studies centered on the identification of push and pull factors influencing the migration of health personnel. Pull factors are associated with the country of destination and include better remuneration and working conditions, prospects for career development, job satisfaction, security. Push factors are associated with the country of origin and include the low level of income, poor working conditions, the absence of job openings and social recognition, oppressive political climate.

Push and pull factors are closely connected with economic environment and the possibilities of advancement. As opposed, the “stick factors” are linked with personal or social aspects of life (Tjadens, Weilandt and Eckert, 2013:47). “Grab factors” are also mentioned in the literature, tied with developed countries (Muula, 2005).

*What impact has medical professionals' emigration?* One of the main factors for the economic growth and human development in a developing country is the size and quality of the health sector (Docquier and Rapoport, 2009). Moreover, the efficiency of a health system is dependent on its human resources (both quantity and quality). Many studies concluded that the medical brain drain is the major factor contributing to insufficient medical personnel, whose consequences are affecting not only health

systems in donor countries, but also the economic development and the national security.

The negative impact on health systems, health personnel scarcity and disparities between regions, the fight against HIV and AIDS became a growing concern (Mullan, 2005). Developing countries confront with the loss of the financial investments in creating health professionals and their most valuable intellectuals in the benefit of developed nations. The emigration of a medical professional represents a loss of US\$184,000 to Africa (Rutten, 2009). On the other hand, according to Van Hoek and Gish studies, emigrants from developing countries are treated as “dispensable commodities”, used only when necessary and the quality of their training is considered to be inferior, thus transforming the native medical personnel into preferred candidates (Wright, Flis and Gupta, 2008).

Beside all these negative consequences, recent literature raised the possibility of a “brain gain” for the developing countries – in terms of remittances, diaspora externalities, return migration.

Remittances contribute to the development of the donor country. Money send back to family can contribute to further investments in education, in the attempt of emigration prospects. The tendency of physicians is to migrate permanently and to bring their family with them in the destination country, and consequently the remittance level is lower than in the case of low-skilled workers. However, for countries like China, India, Philippines, Egypt and Cuba, remittances are considered important source of revenues (Rutten, 2009).

Scientific networks facilitate the movement of people, goods, ideas between sending and receiving countries. Also, they contribute to the increase of foreign direct investments inflows (Docquier, 2006)

Return migration is another source of “brain gain”, medical doctors returning in their country of origin with the experience and knowledge acquired in developed world. Emigrants’ return constitutes a potential source of growth for the donor county (Docquier, 2006). The main problem is that the available equipment and working conditions in developing countries are not adequate to the skills they gained during their training abroad. In this case, the big challenge consists in identifying the best methods that should be implemented to stimulate return migration and transform it into a benefit.

*What measures could be adopted to stem the medical brain drain?* As the medical brain drain represents a global and growing concern, resulting from a combination of push and pull factors the measures to stem it should be addressed at global level and should be the result of an agreed participation of developing countries, developed ones and international organizations (Pang et al, 2002).

Developing countries’ action may include better salaries and working conditions, security and career opportunities in order to reduce the emigration rate, or incentives to stimulate return migration. Current political and economic situation of donor countries combined with the freedom of medical doctors to move, study and practice wherever they want, make this policy option an illusory one.

Measures that could be implemented by the developed nations include: self-sufficiency, financial compensations paid for the skilled workforce received from developing countries and agreements forbidding the recruitment of health professionals from those countries already suffering from scarce resources. Some measures have already been implemented, like the Global Code for Practice for International Recruitment of Health Personnel, implemented in 2010 (WHO, 2011).

The reaction of international organizations (such as World Health Organization, International Organization for Migration, World Bank, United Nations) should consist in collaboration and common efforts in the adoption of ethical guidelines in the fight against this disastrous phenomenon (Pang et al, 2002).

## **Conclusions**

This study offers a review of the literature on the brain drain and medical brain drain starting with the early contributions (from 1950s) until present. The first attempt is to identify similarities between the two phenomena. The three stages of research highlighted in the brain drain literature can be identified to some extent in the medical brain drain literature. Offering a survey of the most important contributions, this study may represent the starting point for future research with regard to the possibility of transforming the brain drain into a brain gain.

A historical evolution of the outflows of skilled emigrants in general and medical doctors in particular showed same trends from 1946 to present. The main limit identified is the lack of accurate and comparable statistical data, mostly in donor countries, thus leading to difficulties in identifying the magnitude of the phenomena. The research done so far is a proof of the fact that the first step in dealing with medical brain drain has been accomplished: the awareness. Future research may focus on the measures to be adopted, area in which little has been done.

A third way of development in this domain can be the debate over the ethics of health professionals' emigration. The free movement of people is supposed to bring benefits for both developed and developing countries, but the reality seems to be far away from this: the disparities between countries are growing constantly, the world being divided between "winners" and "losers", between core and periphery. Industrialized nations compete in attracting the highly skilled while donor countries confront with the loss of their most valuable intellectuals and the investments in their education.

# POLAND'S OUTWARD FOREIGN DIRECT INVESTMENT

**Buczowski Bogdan**

*International Trade Department, Faculty of Economics and Sociology, University of Lodz, Lodz, Poland*

**Abstract:** *The paper contributes to the discussion of motives, determinants and effects of outward FDI of companies from emerging economies. We analyze the the scale, structure, geographical location and effects of Polish foreign direct investments as well as we prioritize their determinants. The interest of Polish companies in investing abroad has increased sharply over the last decade, due to the need to broaden the scale of business operations and geographical scope of their economic activities after the Poland's accession to the European Union.*

**Key word:** *Poland; active internationalization of enterprises; outward foreign direct investment; FDI impacts; FDI determinants*

**JEL classification:** F21

## 1. Introduction

Internationalization of business entities through FDI relationship significantly increases the scale of the local economy with the global system of production and is an important part of building its international competitiveness. Foreign direct investments have been a major factor contributing to the Polish economic growth. The socio-political and economic transformation that has taken place over the last 20 years completely changed the conditions for the functioning of Polish companies, which in recent years increasingly decide to invest abroad, because in the course of their development, the natural need to broaden the scale of operations and the geographical scope of their activities appeared.

The aim of this paper is to identify and prioritize determinants of foreign direct investments made by Polish companies and show their geographic directions of and industry profile and barriers to expansion capital.

There is no one theory that explains the process of internationalization of companies entirely, so it is necessary to use the achievements of various theories together. Selection of the appropriate theoretical framework for the study of various aspects of the country's investment expansion, also depends on what aspect of internationalization is analyzed. For the analysis of international economic expansion, in terms of the home or host country, the mainstream macroeconomic theories are used. Theoretical concepts explaining the phenomenon of FDI at the macro level (Dunning, 1981, 1986; Ozawa, 1992) indicate that the economy has to reach a certain threshold level of development, to be able to become an exporter of FDI. Comparative advantages currently held by Poland are specific to the phase of international expansion, so it can be concluded that in selected sectors of the economy, this level has already been reached.

If the analysis of internationalization applies to the company, the more relevant are microeconomic concepts (Caves, 1996; Knickerbrocker, 1973; Spencer, 2008) that emphasize the specific competitive advantages of individual companies undertaking FDI. They can be of economic nature as well as of psychological and behavioral one. They include the theory of the firm and of market structure. Common feature of

microeconomic theories is the assumption that because of the need to operate in a different political, economic, institutional (Cantwell et al., 2010; Dunning and Lundan, 2008), legal and cultural environments, companies, undertaking international expansion, incur additional costs, which must be compensated in surplus. The reasons for international expansion are as many as the number companies being involved in it, but it is also influenced by the specificity of the sector, as well as by the driving forces of globalization (Porter 1996; Yip, 2004). Thus, the foreign expansion of companies depends on a number of motives like: high profits, business growth or motives that determine the achievement of such goals. The reasons for internationalization boil down mainly to the implementation of the objectives pursued by the company. Types of motives and their classification are very diverse, but the most distinguished are: market conditions (economic, business), costs, resources - in particular the acquisition of strategic resources - and political ones.

## 2. FDI size and growth

Since the beginning of this century, the investment activity of Polish enterprises at the world economy has been growing significantly. By the year 2000 Polish cumulative value of direct investments abroad (FDI) amounted to only 1 billion USD (see Figure 1). The rapid growth was observed after the accession of Poland to the European Union in 2004, with the record high of 9.2 billion USD in 2006. Now, after a decline, in relation to the global financial crisis, Polish FDI regain their momentum i.e. 7,3 billion USD in the year 2011 (see Table 1), increasing the cumulative value of to 49,7 bln USD in 2011 and 57,5 bln USD in 2012. This means that in the past 5 years of the financial crisis, the cumulative amount of funds invested by Polish companies rose by over 200%. In terms of outward investments Poland is in the 44th place in the global league table.

It is worth mentioning that a large part of Polish foreign investments are made through the companies located in countries with favorable tax regulations or/and favorable to the formation of the holding structures, which means that the official statistics do not account for a large part of such investments.

## 3. Geographical location

Polish firms have invested mainly in Europe (92,4% of all FDI – see Figure 2). They have carried out 78% of investments in the wealthiest, demanding and highly competitive the European Union markets (see Figure 3).

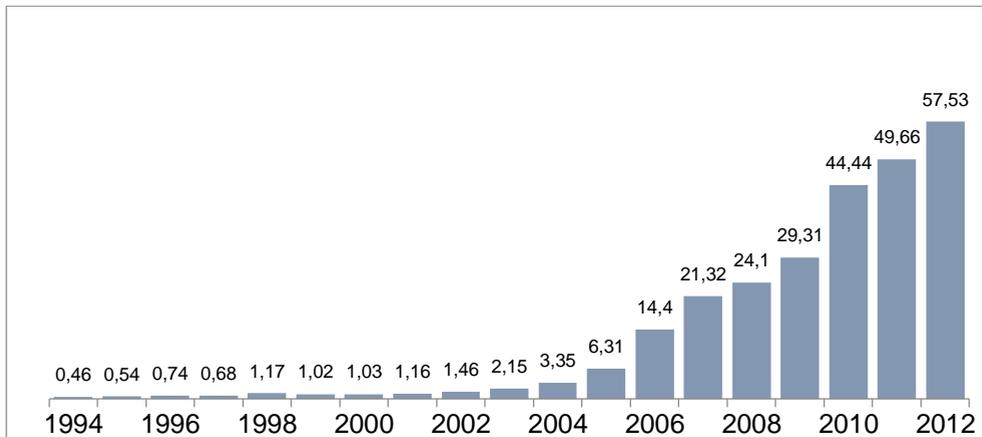

**Table 1:** Polish direct investment abroad in millions of USD (net transactions)

2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
16	-90	230	305	955	3392	9168	5664	4613	4562	7484	7335

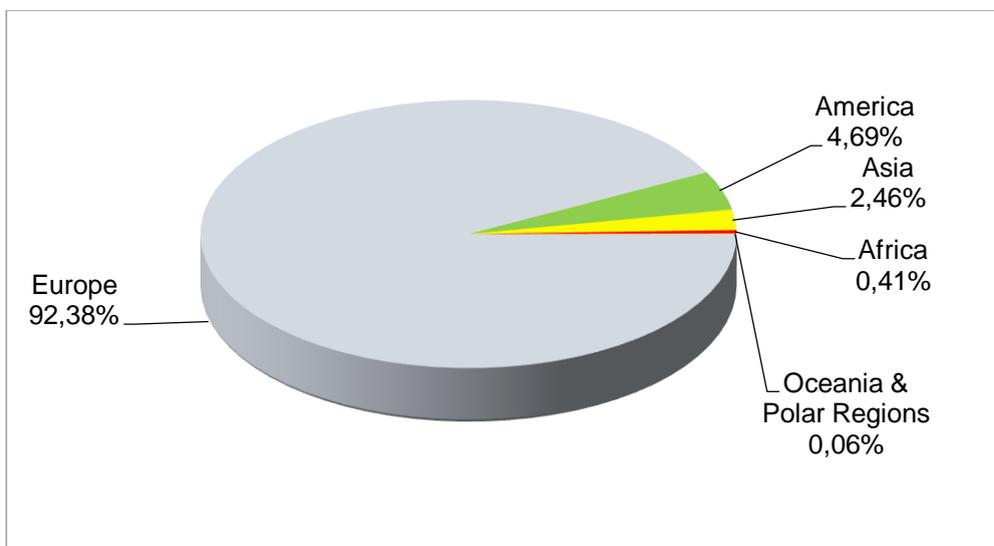

Source: Balance of Payments Statistics, National Bank of Poland, <http://www.nbp.pl/home.aspx?f=statystyka/statystyka.html>.

However, most of these investments, in particular in Luxembourg, Belgium (and non-member Switzerland) are primarily financial in nature and associated with the capital structure of companies, transactions at third markets and tax issues. Luxembourg, that is perceived as a transit country for investments, has attracted 30,6% of Poland's cumulative FDI in the EU (or 23,8% of all Polish FDI), ranking ahead of Britain with 14,2% and two other transit countries i.e. Cyprus with 8,4% and the Netherlands with 7,8%, Belgium 7,1%. Lithuania with 6.4%, the Czech Republic with 6.3% and

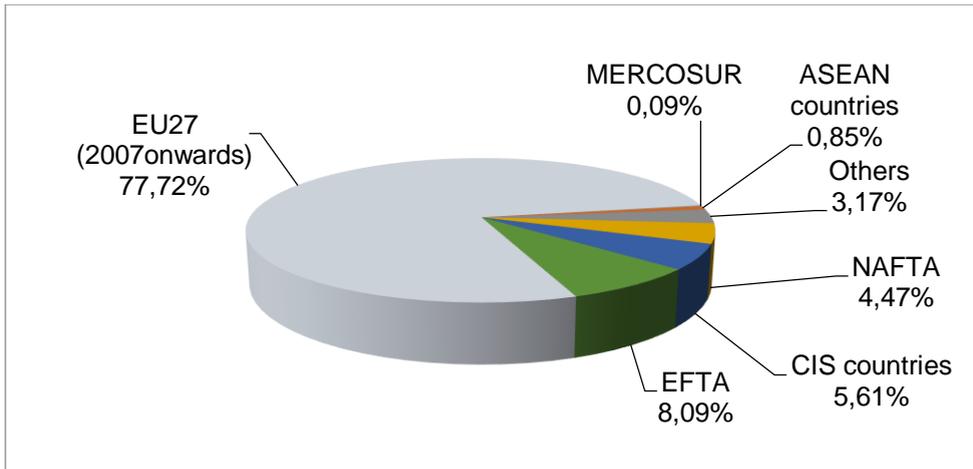

Germany with 5.4% (see Figure 4). The most common directions of all Polish FDI is also Ukraine, USA, Russia and Romania.

#### 4. Distribution by sector

The investments are most highly concentrated in the service sector, which accounted for 53,5% of total cumulative FDI and 57,2% of total income on FDI in 2011, as well as in manufacturing sector that accounted for 34,6% of FDI and 15,1% of total income on FDI (see Figure 5, 6). Three industries stand out in service sector. Firstly, the professional, scientific and technical (holding activities) that accounts for 39,6% of FDI in services (20% of all cumulative FDI), but giving relatively small fraction of sectoral income, i.e. 7% and 4% of total income in 2011 (22% and 16% in 2010). Secondly, financial and insurance activities that accounted for 30,2% of sectoral FDI (15,3% of all FDI) and 60% of sectoral and 36% of total income on FDI. Thirdly, wholesale and retail trade, repair of motor vehicles and motorcycles that accounted for 21,4% of sectoral investments (10,9% of all FDI) and 18% of sectoral and 11% of total income on FDI (see Table 2).

Four industries stand out in manufacturing sector. Firstly, refined petroleum products and coke that accounts for 21% of sectoral FDI (7% of all cumulative FDI). Secondly, vehicles and other transport equipment that accounted for 14,9% of sectoral FDI (5% of all FDI) and 55% of sectoral and 9% of total income on FDI. Thirdly, food products, beverages and tobacco products that accounted for 14,3% of sectoral investments (5% of all FDI) and 20% of sectoral and 3% of total income on FDI. Fourthly, basic metals and fabricated metal products that accounted for 11,4% of sectoral investments (4% of all FDI) and 27% of sectoral and 4% of total income on FDI (see Table 3).

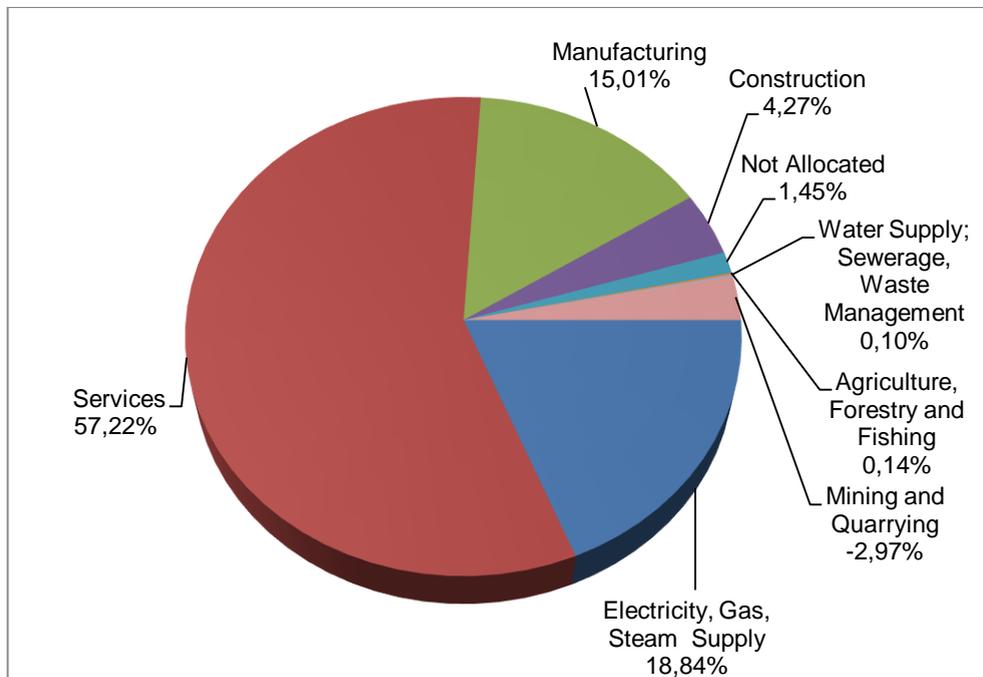

**Figure 5:** Polish cumulative FDI outward position at the end of 2011 broken by economic activity of the non-resident direct investment enterprise

Source: own calculations based on National Bank of Poland data, <http://www.nbp.pl/home.aspx?f=/statystyka/statystyka.html>.

Taking into account FDI/income ratio in service sector, the most income bringing were investments in financial and insurance activities, education, and wholesale and retail trade, repair of motor vehicles and motorcycles. Professional, scientific and technical activities, in which cumulative FDI have been the highest ones, FDI/income ratio was very low (see Table 2). In manufacturing sector the highest FDI/income

ratio was in chemicals and chemical products industries, vehicles and other transport equipment, machinery and equipment, and basic metals and fabricated metal products. The lowest ratio was in refined petroleum products and coke industries in which cumulative FDI have been the highest ones in manufacturing sector (see Table 3).

**Figure 6:** The share of sectors in total income on FDI at the end of 2011

## 5. Characteristics of Polish companies investing abroad

1443 Polish entities (in 2010) located their capital in 2988 foreign units in 96 countries. 2512 by acquiring shares, 358 by setting up branches, 84 setting up plants and 34 in other forms. They had direct shares in 2339 foreign units, indirect shares in 560, and both direct and indirect shares in 89 foreign units. In 1782 units they had 100% shares, in 598 from 50.01% to 99.99%, and in 608 units - up to 50%. 926 of 1443 entities, that had branches and subsidiaries abroad, were limited liability companies, 438 – joint-stock companies, 25 - general partnerships, 17 – 37 were

limited partnerships and entities organized in other legal forms. The largest number of entities (488) were dealing with manufacturing (in their 921 foreign subsidiaries), 328 entities with trade and repair of motor vehicles (in 709 international units), 189 with construction (in 288 international units), 113 with professional, scientific and technical activities (in 258 international units). 1146 out of 1443 entities belong to groups of enterprises, 1802 were located in all EU countries. Approximately 52% of foreign entities were established in all seven bordering countries. Most of the foreign units were headquartered in Germany - 400, Ukraine - 356, and in the Czech Republic and Russia - respectively 246 and 231. The total number of employees (in all 2988 foreign units) amounted to 148,1 thousand foreign people, of which the largest share was in manufacturing sector (32.1% or 47.6 thousand employees). Exports of products, goods and materials, by foreign entities, amounted to 29,03 bln PLN. The largest share belonged to manufacturing units (85.7% or 24,9 bln PLN). Exports to parent company and to the subsidiaries within the group of companies amounted to 8,1 bln PLN (28.1% of total exports by foreign entities). The value of imports, carried out by foreign units, amounted to 44,6 bln PLN. As in the case of exports, the highest share of imports (83.5% or 37,3 bln PLN) belonged to the entities operating in the field of manufacturing. In contrast to exports, imports from parent and affiliated companies accounted for the vast majority of imports of foreign units (82.5% or 36,8 bln PLN). The investments in tangible fixed assets amounted to 3,7 bln PLN. The largest expenditures on assets incurred in foreign units engaged in manufacturing - 1,2 bln PLN or 32.5% of total expenditures (Działalność podmiotów, 2012).

The nature of business was different in the case of 1223 foreign entities (of all 2988) as compared to the basic economic activity of the Polish parent company, while in 1765 units was consistent with the type of business carried out by the Polish entity. Distribution of the number of foreign units according to their activities was as follows: 986 (33.0%) units were involved in the trade, repair of motor vehicles, 535 (17.9%) in manufacturing, 347 (11.6%) in construction, 260 (8.7%) in professional scientific and technical, 239 (8.0%) in transport and storage, and 621 (20.8%) in other types of activities. The largest revenues from sales of products, goods and materials were achieved by foreign units engaged in manufacturing (53,4 bln PLN), and in trade and repair of motor vehicles (35,4 bln PLN). Taking into account the location of the foreign units, the highest revenues were achieved by international units based in the Czech Republic – 24,2 bln PLN and in Germany – 24,2 bln PLN. The biggest exports and imports also fell into units which were engaged in manufacturing, and trade and repair of motor vehicles, respectively export – 24,4 bln PLN and 2,5 bln, and imports - 40 bln and 12,6 bln PLN.

## **6. Motives and perceived effects of investments**

The main motive for the investment decisions of Polish companies is the size of local market (86% of all FDI are in the EU and EFTA. See Figure 3). Relatively important is also the level of competition in target markets, the geographic and cultural proximity, the size of local resources, the low risk and political stability. A large geographical distance is a factor negatively influencing the investment decisions (see Figure 3), in the case of greenfield investments and acquisitions by companies in the production and industrial sectors, but it does not matter for services companies (Kowalewski and Radło, 2012). In particular, companies prioritize the reasons for investing abroad as follows:

1. access to the local market, 2. poorer, 3. increase in global market share, 4. blocking competition, 5. competitors has already done so, 5. access to local brands, 5. global market access, 6. access to local technology, 7. competition lower than in Poland, 8. diversification of product portfolio, 9. cheap labor, 10. business environment better than in Poland, 11. optimization of supply chain, 12. exchange rate prevention, 13. higher quality of human resources, that is an important factor when deciding on greenfield investments, and only to a small extent important in the case of brownfield ones (Polski Czempion, 2012). So, in the hierarchy of reasons, a development motive (access to foreign markets, or simply an increase in sales) prevails. High on the list is "global" motive, what means that many Polish companies have already recognized themselves as current or potential players in the world market. Significantly low position in that hierarchy occupy cost and efficiency motives. Investors perceive the effects of their investments as being poorer-than-expected, in the case of access to the local market and growth of the company, slightly poorer in the case of global market access and blocking competitors (Aktywność inwestycyjna, 2012). However, significantly higher-than-expected are perceived effects as to: diversification of product portfolio, cheap labour and competition lower than in Poland. The rest effects slightly exceed expectations. The main barriers and challenges in investing abroad, identified by Polish investors, are: cultural differences, organizational and administrative burdens and corruption in the host country). Also important are language barriers, problems with the distribution at local market, high operating costs and the lack of qualified workers (Polski Czempion, 2012).

Many Polish companies point out that thanks to foreign investments are able to maintain or even boost sales, what often would be impossible without entering new markets and without creating new production capacity. They also obtain the stability by becoming less dependent on the situation at the domestic market, and get greater access to raw materials. Thus, foreign investment is a way to ensure the diversification of market risk related to the demand for company's goods and services, as well as the risk related to the security of a supply chain.

Polish firms, investing in the Far East and eastern markets, have competitive advantage in products and services that have been perceived as being of good quality for a long time. The fact that Poland is the member of the European Union strengthens its investors, that are perceived as serious partners providing world-class products. Many Polish entrepreneurs combine knowledge and experience, acquired in the course of over 20 years of transformation, giving them a clear advantage in less developed countries, that are still undergoing such transformation, over the competitors from well-established Western countries. They are able to work in a less stable and supportive institutional and administration environment. They show relatively high flexibility due to the smaller size and shorter decision chains, so they are able to respond quickly to changing market conditions and to adapt their products to the current market situation. The economic crisis may help Polish entrepreneurs to gain entry into foreign markets, as many buyers, even in developed markets, resign from expensive branded products and are looking for goods and services with the same quality, but at a lower price. Such a situation fosters the promotion of new brands (Polski Czempion, 2012).

## 6. In conclusion

The analysis showed that the Polish outward direct investments are made, as a rule, in Europe and the most popular investment directions are the European Union countries. The transfer of business operations abroad is due to financial surpluses, increased competitiveness and limited capacity of the Polish market. FDI are not nearly motivated by the search for natural resources, reduce the cost or by favorable taxation. Polish OFDI has the tendency to increase in parallel with its economic growth. They are largely commercial in nature and are intended to support exports in the form of commercial offices and retail outlets. Thus, the outflow of domestic capital does not substitute for exports significantly so it is not very likely to influence negatively Polish economy.

**Abstract:** *Local communities embracing the concept of Eco-industrial park are looking for some additional benefits for all the interested parties – both public and private: higher economic efficiency, the increase of competitiveness by applying last minute technologies, generation of additional revenues through positive regulations at the community level, the creation of jobs, solving the conflict between economy and environment, diminishing the demand on the county infrastructure, decreasing the effects of pollution, using energy from regenerating sources and replacement materials. Communities and enterprises creating Eco-industrial parks will have common grounds for industrial development, which is much more competitive, more efficient and much cleaner than traditional industrial parks. Moreover, the new business niches will be open to recruitment or new incubators. Eco-industrial parks represent a special category compared to industrial parks, a category which is different from the classical ones due to the fact that they are designed in such a way so that they promote the collaboration between companies in order to reuse recyclable materials and green energy sources. A long-term vision must reflect the focus on the creation of collaboration networks between firms and the fact that an Eco-industrial park should be a business community, not only a mathematical sum of companies located in the same geographical area. The quality, continuity and interconnection of economic flows within the firms of an Eco-industrial park are important characteristics for the success of Eco-industrial networks. The following discussion tackles the way in which an Eco-industrial park is set-up: creating and implementing an Eco-industrial park in accordance with the principles of circular economy or transforming an already existing industrial park into an Eco-industrial park. The quality, the continuity, the number of interconnected firms, the flows of resources and the relations between the firms are success factors within Eco-industrial networks. The successful cases – especially those in the USA or the Northern countries – have proved that Eco parks engage a multitude of entities, from regional/local authorities to non-governmental organizations; in these entities' action the objectives and actions of the firms; management overlap with those of the community management.*

**Keywords:** eco-industrial park, resources, circular economy, local community , sustainable development

*JEL classification:* F21, F22

### **1.Introduction**

In the last decades, high technology industry was connected to the regional development and the involvement of local communities. The running of some economic-industrial activities based on high technology processes was concentrated in certain areas, known by the name: industrial parks, industrial areas, technological parks, scientific parks, business centres, technological districts or industrial districts.

Such areas are many times associated to concepts like economic growth poles of multiplication effects.

An industrial Eco park can be defined as a business community (production, services etc.) which seeks to improve its economic, social and environment performance in concert with the administration of human, financial and material resources.

The purpose of an Eco park is to improve the economic performance of participating firms, reducing to a minimum their negative impact on the community, environment and other interest groups.

Communities and enterprises creating eco-industrial parks will have a common ground for industrial development, which is much more competitive, more efficient and much cleaner than traditional industrial parks. Moreover, the new business niches will be open to recruitment or new incubators.

Local communities embracing the concept of Eco park are looking for some additional benefits for all the interested parties – both public and private: higher economic efficiency, the increase of competitiveness by applying last minute technologies, generation of additional revenues through positive regulations at the community level, the creation of jobs, solving the conflict between economy and environment, diminishing the demand on the county infrastructure, decreasing the effects of pollution, using energy from regenerating sources and replacement materials. The Eco parks can generate benefits both for the local-regional community as well as for the companies operating there; these benefits are given by the recovery of resources, more ecological production, lower environment taxes, high company productivity, government facilities, interaction system among the firms, etc. The eco-parks should be conceived so that they can support the implementation of this whole system.

## **2. What is an "industrial Eco park"?**

An eco-industrial park is a community of manufacturing and service businesses in which member businesses seek enhanced environmental, economic, and social performance through collaboration in managing environmental and resource issues. By working together, the community of businesses seeks a collective benefit that is greater than the sum of individual benefits each company would realize by only optimizing its individual performance (Lowe, Ernest A. 2001).

The Eco-industrial parks can be best defined as business communities that cooperate with each other and with the local community to efficiently share resources, subassemblies and reuse of waste from partner firms (Côté and Cohen-Rosenthal 1998).

The definition provided by Peck and Ierfino associate the Eco-industrial parks to Eco-industrial development or the industrial development. We are talking about parks in which there is material and energy cycling, the waste or the output of one firm essentially becomes an input into the production process of another firm. All these waste exchanges result in cost savings and revenues for the firms. (Peck, Steven & Ierfino, Laura. 2003)

An Eco-industrial park (EIP) is a community of companies, located in a single region, that exchange and make use of each other's by-products or energy (Desrochers 2002).

An Eco industrial park is an entity, designed and managed according to the idea of Circular Economy and the theory of industrial ecology. Through their own

management system, the companies are connected to form a complex in which the products or waste of one company can become the raw material or resources of another company. (SEPA 2003).

The Eco-park can be perceived as an instrument to ensure the industrial development in urban areas, quantifiable through the benefits of the local communities in the economic, social and environmental area.

The Eco-industrial parks represent a special category compared to industrial parks, a category which is different from the classical ones due to the fact that they are designed in such a way so that they promote the collaboration between companies in order to reuse recyclable materials and green energy sources. In this view, in an Eco-industrial park, the way in which a company operates its production is taken into consideration when ensuring the park's general maintenance activity so that it gets through the synergy of different companies to an ecosystem from the point of view of resource use and optimize the energy consumption.

Gibbs and Deutz (2004) concluded that the Eco-parks do not merely mean a simple eco label or a green dot, but "the existence of a network of inter-organizations and the collaboration as transfer of materials and energy flows so that maximum efficiency in using the resources should occur.

The necessity of Eco-parks appeared in the countries or regions which had a very high degree of industrialization and, therefore, they were confronted with rapid resource weariness. The main advantage of an industrial park implies a physical change of materials, water and by-products (Chertow 2000).

To be able to speak about a real Eco-industrial park, a development should be bigger than: a single by-product exchange or network of exchange, a recycling business cluster, environmental technology companies, companies making "green" products, an industrial park designed around a single environment theme (for example a solar energy-driven park), a park with environment friendly infrastructure, a mixed-use development (industrial, commercial, and residential) (Lowe 2001).

We must admit that the notion of Eco-industrial park is not a concept related to environment and ecological problems. The purpose of these entities is to generate wealth for the firms and communities of people by better using resources and, paradoxically, of waste. Sometimes it is very difficult to bring to a common denominator the needs and interest of the firms, local communities, local authorities and interest groups. The role of these eco-industrial networks is to solve the "conflicts of interests" between different players who might be involved in the sustainable development of a particular area.

### **3. Influencing elements in the development of eco-industrial parks**

If the notion of industrial park has already been introduced all over the world, the eco parks aspire to be a superior economic activity stage, which covers all the drawbacks of excessive industrialization and the less sustainable use of everything meaning resources. The comparative advantages of eco-industrial parks compared to classical industrial parks result from the way they are conceived and implemented:

1. Existence of the community of interests and involve that community in the design of the park
2. Reduce the negative environmental impact through substitution of toxic materials, material exchanges and integrated treatment of wastes.
3. Maximize energy efficiency through appropriate system design.
4. Reuse, recovery and recycling materials between partner firms.

5. Link or network companies with suppliers and customers where the eco-industrial park is situated.
6. Continuously improve the environmental performance by the individual businesses and the community as a whole.
7. Have a regulatory system which permits some flexibility.
8. Use economic instruments which discourage waste and pollution.
9. Existence of an information management system which seeks to train and educate managers and workers about new strategies, tools and technologies to improve the system.
10. Marketing strategies to attract companies which fill niches (Côté and Cohen-Rosenthal 1998)

The premises for the design and success of an Eco –industrial park are: integration within natural systems – the design of eco parks in harmony with the characteristics and constraints of local ecosystems; energy systems – the large-scale use of regenerating sources, the reuse and recycling of materials among the enterprises in the Eco park; the identification of companies in the region as consumers and generators of secondary useable products through resource and recycling network exchanges; information management systems – the existence of an exchange of information between companies on the local environment conditions, community, feedback on the performance.

A long term-vision must reflect the accent regarding the creation of networks of firm collaboration and that an eco-industrial park should be a business community and not just a mathematic sum of companies located in the same geographic setting. The success factors for an eco-industrial park are: geographic setting, close proximity of companies, exchanges of materials and energy, diversity of players, continuity of flows, economic viability, low economic risks, economic gains are shared approximately equally, existing institutional regulations, environmental awareness in the firms, balanced interdependence relationships between partners, similar organisational cultures of firms, active participation, commitment, trust, vision of the Eco-industrial parks, contracts / informal control mechanism, legal support, political support (Gibbs & Deutz 2004).

There are limits in creating eco-industrial parks: the firms in an industrial park can have similar fields of activity and, therefore, will generate similar products (thus, there will be relatively little ways to reciprocally use the secondary outputs of products and to discuss the reuse of outputs), the firms have limited time to negotiate the transactions necessary to use the non-marketed products of the partner firms in the Eco park (the cost to reach an agreement – and minimizing the risks – can be higher than the value of the material or energies used), the exchange of by-products is an end-of-pipe solution which can diminish the efforts of the firms to restructure the processes or the product design.

The role of resource recovery within an eco-industrial park can be, many times, as important as reaching a high level of efficiency in using regional resources. This group of firms can include: niche firms to capitalize the outputs of some large companies, production firms to use recycled materials, firms which can ensure the reuse of production machines and systems, firms to rehabilitate the equipment used and energy plants to generate fuel or non-conventional energy or regenerating energy.

The appearance and development of eco parks can transform into leverages supporting the concept of Circular Economy. The concept of Circular Economy

emphasizes the benefits of utilizing residual waste materials through the development of some complex interconnections between firms (Jacobsen 2006). The implementation of some circular economy elements promotes the minimizing of the amount of discharged waste and the adoption of ecological technologies in the economic processes (Andersen 1997, 1999).

According to Zhao and Lowe, the three main levels of a circular economy are:

- The first level, managers must seek much higher efficiency through the three Rs of CP, reduce consumption of resources and emission of pollutants and waste, reuse resources, and recycle by-products.
- The second level is to reuse and recycle resources within industrial parks - clustered or chained industries, so that resources will circulate fully in the local production system.
- The third level is to integrate different production and consumption systems in a region – area, so the resources circulate among industries and regional systems (Zhao and Lowe, 2004).

#### **4. Management of an eco-industrial park**

An eco-industrial park is a clearly defined area where there are exchanges of materials, energy and information between different companies and local players. Eco-industrial parks can be planned for a totally new field or for operations developed around some already existing economic processes. The quality, continuity and interconnection of flows between the firms of an Eco-industrial park are important characteristics for the success of eco-industrial networks. The trust, communication and management relations are, also important. An Eco-industrial park is the most appropriate for the mature companies in a field among which there are already institutional or collaboration relations.

The management of an Eco park may face different rejection or influence forces. These barriers have been identified and classified by Heeres into five different Types (Heeres et al 2004):

- Technical barriers – when the exchange is not accepted by the community and the interest groups
- Economic barriers - include economically unsound or risky exchanges.
- Informational barriers - arise when the information are not accurately or transparently enough presented by the project initiators.
- Organisational barriers - when the rules of the Eco-park do not match the firms' corporate rules.
- Regulatory or legal barriers.

Eco-industrial parks are entities which can work only based on a very efficient management, a management which starts with the projection stage and, implicitly the finding of some companies which will become partners and which can generate among them connections in utilizing the inputs and outputs. All the management actions of an Eco park converge in the three fundamental directions: economic responsibility, ecological responsibility and social responsibility.

Lowe (2001) identified the main management tasks of an eco-industrial park:

- Finding new forms of cooperation between partner firms and other interest groups
- Enhancing the dialogue between partners
- Maintaining and managing services

- Supporting material and energy flows
- Recruiting new companies
- Improving the environmental performance of the park and companies
- Maintaining an information system
- Linking companies and public organisations

The following debate is related to the way in which an Eco-industrial park is set up: creation and implementation of an Eco-park according to the principles of Circular Economy or the transformation of an industrial park – already existing – into an Eco-industrial park. The successful cases – especially in the USA or Northern countries – have demonstrated that Eco-parks engage a multitude of entities, from regional/local authorities to non-governmental organizations; in their action the objectives and actions of the firm’s management overlap with the community management.

Salonen (2005) presents two management models of Eco- industrial parks: the “major user model” and the “infrastructure company model”. In the first case, a major investor in the area owns the land of the site, leases estates to companies and works as a coordinator. In the second situation, the investors are the shareholders of the company operating in the area. In both cases, the difference from an industrial park is related to the way in which the flows of resources and waste are utilized and managed.

There can be cases when the Eco-industrial network will be built around a powerful company, an anchor tenant which links actors in the park, by-producers or service suppliers. The only condition in this case is that the mission of this corporation and the management strategies lead towards a Circular Economy behaviour.

Another situation occurs when the central entity of this Eco-industrial network is a public agency – either regional or local. The advantage of this organization lies in this public agency’s institutional and legislative capacity to provide political, legislative and institutional support, especially in fields related to the flows of resources and waste reuse. Agenda 21, as an instrument of sustainable development of a community can thus contain such eco-industrial networks.

In spite of all these, we cannot state that there is a template-model for a successful Eco-industrial park. The framework –conditions for Eco-industrial networks are considerably different from country to country and within them. It is important to evaluate the needs of the community and of the partner firms and according to these to create a model of sustainable park. The parks should be integrated in an innovation regional framework which recognizes the characteristics and the innovation qualities of the environment in the region and, also the local government competences and capabilities. Regional-local authorities, other institutional entities and firms interested in developing a park should create together an organization basis.

## **5. Conclusions**

The experience of classical industrial parks, which put together firms with interests, with totally different corporate culture and managerial procedures and strategies, provide us with a multitude of successful or unsuccessful examples given by a poor business environment, pollution, traffic congestion, irrational exploitation of resources. The fact that over 75% of the Europeans live in the urban area has led to the increase of pressure on the local resources, including these industrial spaces

where the enterprises are or should grow and become prosperous. Although there are many industrial parks which are developing (as demonstrated by economic indexes), they operate in a totally unsustainable manner. This growth is generated precisely by an irrational and excessive exploitation of the resources of the area/region. Eco-industrial parks do not come to fill these drawbacks, yet they determine local community/ interested parties to consider the development strategy of the area and of the firms involved in accordance with the principle of rational joint use of the resources it has. The capacity to innovate and intensify the relations between different players is the main feature of this new approach.

[isechel@yahoo.com](mailto:isechel@yahoo.com)

**Abstract:** *In this article we propose an easy approach of stock exchanges and their impact on the real economy. The paradoxes of modern stock exchanges are commonly understood as opinions that contradict the generally accepted truth and therefore are considered absurdities or huge enormity by the majority of the population.*

*The paradoxes are essentially based on logical arguments that sometimes can lead to contrary or contradictory conclusions (depends on the situation) of a truth already known and accepted. In connection with capital market, through this approach we try to highlight a few aspects that come out from everyday life, breaking the monotony of theoretical resolutions.*

*We can associate anomalies in trading financial instruments with prove that financial markets are inefficient. They can be highlighted best on the developed financial markets. Through their specific, there are anomalies in a stock market that demonstrates either that the market is inefficient or that there are some discrepancies regarding certain asset price formation. If we talk about market inefficiency hypothesis, it is demonstrated that in that market, the efficiency of the market is not verified or partially verified. It has been shown that such anomalies tend to diminish or even disappear in time, thereby reducing or even eliminating the profit opportunities of the investors who speculate on them (Schwert, 2003, p 940). The stock exchange anomalies, especially those with a direct impact on the financial instruments price which are traded on stock exchanges, are likely to offer investors the opportunity to obtain above-average market gains, in term of a proper management.*

*To assess whether or not the phenomenon can be considered as a stock market anomaly, it must be compared with a normal behavior or with a normal model. In addition to the main categories of stock market anomalies that we identified (calendar, technical or fundamental) a paradox of recent years in the investment in stock market is the high-frequency trading (HFT - high-frequency trading), this requires a ultra-fast trading of the securities, using special algorithms but also highly advanced technologies. The effects of very rapid extension of these practices are reaping huge profits in fractions of time increasing fraction of time here, and more than that the pronounced weakening of the link between the stock market and the real economy.*

**Keywords:** *stock market paradox; high-frecquency trading, january effect, weekend effect.*

**JEL classification:** *G02; G12; G23;*

## **1. Abnormalities in the financial instruments trading through stock exchanges.**

Although that in the history it can be identified moments when stock exchange abnormalities seen in terms of inefficiencies in financial markets, it does not mean that they are repetitive or that the frequency of their event follows a certain logic. Thus, investors should be aware of this aspect when they are setting their goals and hopes of winning.

Stock market anomalies and the moments when they occur are identified primarily by investors who closely follow the market and its evolution and also by the researchers in this field. They can see more easily the moments when the evolution of stock prices emerges from what is "normal" and thus creates opportunities for those who observe them. When identifying these situations, they have basically two options to proceed: either they warn that market actors about the findings or take the advantage of market inefficiencies and speculate marking the additional profits into their accounts. In most of the cases their choice is obvious, namely to speculate and take advantage from the opportunities of the market, but whatever their option is, the result is always the same: mitigation and disappearance of the market anomalies.

From our point of view, the anomalies encountered in the financial markets or stock exchanges, can be viewed in terms of time (calendar anomalies), in terms of technical analysis interpretation (technical anomalies), in terms of assessment relating to fundamental analysis (fundamental anomalies) or abnormalities related to other issues. This article addresses only calendar anomalies and high-frequency traders practice. Technical anomalies and fundamental anomalies will be addressed in another article.

## **2. Calendar anomalies.**

Calendar anomalies as apparent from their name, refers to the situation of financial markets inefficiency that can be seen at certain points in time and broadly in line with a temporal logic. The best known such anomalies are weekend effect and January effect. But besides these anomalies we can talk about vacation days anomalies occurring after Halloween, quarterly anomalies, effects in the same calendar month, the Monday effect which is often seen in connection with weekend effect, the effect of intraday trading (in one trading day) or anomalies seen in years ending with the digit "5".

### **2.1. The January effect.**

January effect means that most stock of the world and especially those of smaller capitalization generated high yields (unusually large) in January.

According to Robert Haugen and Philippe Jorion: "January effect is probably the best known example of aberrant behavior encountered in financial markets, around the world" (Haugen & Jorion, 1996). Those two concluded that small cap stock markets have generated higher returns than large capitalization stock markets, the difference between the two categories of stocks being given by the January effect. The smaller capitalization stock exchanges recorded substantial increases of prices of securities listed, in the first 10 trading days of January.

January effect creates great opportunities for speculators, who will buy listed securities before the month of January, and who are expected to sell in this month

with the added value determined precisely by this effect. January effect means therefore initiating long positions before the end of the year at lower prices, and selling them in January at a higher price, the difference between the two prices is the investor's profit.

Like any financial market anomaly, the January effect is seen as a form of financial market inefficiency. But according to the theory of efficient markets, it should go away with the passing of the time. At least so far that has not happened, although some researchers argue that the effect diminished over time (Haugen & Jorion, 1996).

January effect was first observed in 1942 by a banker - Sidney B. Wachtel (Haugen & Jorion, 1996), and the explanations that have been made over time were mainly on the willingness of investors to avoid additional pay taxes on gains from the stock market. Thus, in case of relative losses on financial titles, investors will sell those securities and will assume the loss, for reducing the taxable amount at end of the year. Massive sales of financial titles determine the decrease of securities quotations and also the decrease of prices in the market. However, the same investors will proceed to purchase even of the same titles, in early January, resulting in an increase of prices. The fiscal aspect is discussed by others (Jacquillat & Solnik, 1997, p 70) with the same meaning. Of course, we can find explanations also in the willingness of investors to liquidity their portfolios before the end of the year, so before the winter holidays (for expenses incurred by them). We believe, however, that sales resulting from this last reason do not influence the stock market prices in a very high level, this is because the amounts are insignificant.

Regarding the aspect of taxation, the January effect has been demonstrated by empirical studies on markets in the UK and Australia, countries with fiscal year not ending on 31 December. Therefore, the explanation of "tax-loss-selling" is not credible in this case, which makes us believe that there are other factors influencing the investment process, which causes this effect.

Jason Fink, Kristin Fink and Godbey Janathan analyzed the existence of January effect from the perspective of the size of the company issuing the securities listed and which achieves an improved performance in the months of January (Fink, Fink, & Godbey, 2008). They concluded that smaller companies recorded higher performance in January than the other. Also, in the same study was included another variable - the age of the company (the period since its shares were listed on stock exchange) which seems to have a major importance in the existence of this anomaly. The January effect has been studied by Rozeff and Kinney in 1976, Roll and Keim in 1983 or Lakonishok and Smidt in 1988 (Fink, Fink, & Godbey, 2008), which was tested on many of the world's financial markets. Investors around the world are aware of this anomaly and try as much as possible to take advantage of the opportunities that it creates. Among brokers say that a particular market performance in January predicts a good performance for the rest of the year.

## **2.2. The effect of the end of the month.**

Empirical studies show that it can be observed an increase in yields of listed securities at the end of any calendar month. This aspect was studied by Lakonishok and Smidt in 1988. Their analysis included daily values of the Dow Jones Industrial Average over a period of 90 years, the purpose being to test the existence of seasonal patterns in the rates of obtained return (Lakonishok & Smidt, 1988). Those

two concluded that anomalies can be observed in terms of profitability obtained at the end of weeks, at the end of month, end of the year and around the holidays.

In 1996, Chris Hansel and William Ziemba showed that the effect of the end of the month can be determined by paying of the wages or interest (Hansel & Ziemba, 1996). With extensive study on the analysis of the daily values of the S & P 500 over 65 years (from 1928 until 1993), they concluded that the returns generated by the increasing quotations at the end of the month are significantly higher than their annual average. Their demonstration suggests that investors can take advantage of this anomaly and buy securities before the beginning of a new month, with a few days earlier and then sell them a few days after its beginning.

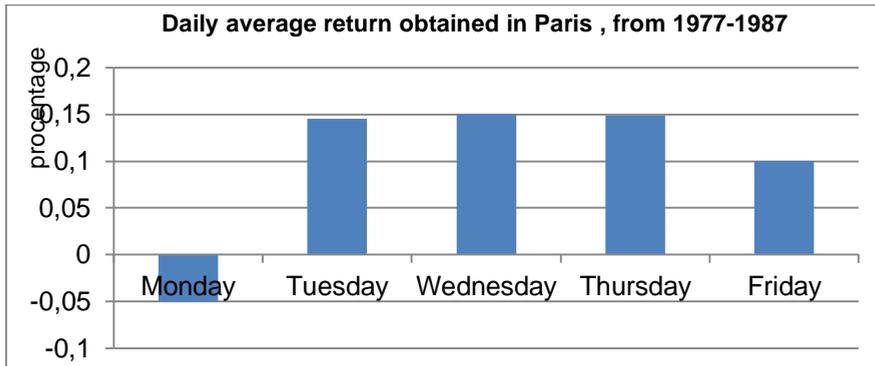

In 2006, in Xu and McConnell's article, which was awarded with the Graham Prize- "Equity Returns at the Turn of the Month", the authors studied the phenomenon for a period of 80 years (from 1926 to 2005) for the Dow Jones Industrial Average (Xu & McConnell, 2006). The conclusion they reached is that the last trading day of a calendar month and the first three trading days of the next month offers higher returns for listed shares than the average annual yield. Those two have demonstrated that the effect of the end of the month seems to be more pronounced in the years after 1986.

From our perspective, the effect of the end of the month is a challenge for what means the rational behavior of investors in the financial market.

### **2.3. The weekend effect.**

The weekend effect was first studied by Fields in 1931 when transactions could be concluded on Saturdays (Fields, 1931). The same Fields showed in 1934 that the Dow Jones Industrial Average shows a tendency to increase the day before holidays. The weekend effect has been studied by many researchers, and the first to correlate this effect with the schedule as it was manifested was Lawrence Harris in 1986. He showed that the weekend effect tends to occur in a significant extent in the first 45 minutes of trading on the day of Monday. Besides, Monday morning seems to be one of the days of the week in which the quotations recorded decreases in value (Harris, 1986).

The weekend effect is often treated in the literature with the Monday effect. The two effects basically relate to the same thing. Hamon and Jacquillat demonstrated in 1988 that Monday seems to be the worst day for investment in shares (Jacquillat & Solnik, 1997). The study realized by them, was based on daily historical values of AFFI SBF index for the period 1977-1987. They found that the average return achieved on Monday was negative and in all other days of the week in which it can be concluded transactions on the stock exchange, the return was positive. For data series, the authors considered the daily opening value of the index.

**Figure 1. Daily average return obtained at Paris Stock Exchange, from 1977-1987**  
*Source: processed after (Jacquillat & Solnik, 1997, p. 72)*

This anomaly involves at least an interesting explanation. The weekend effect appears to be the result of the tendency to publish negative news on Saturday or Sunday. Bad news about the market likely to influence its development, mainly occur on weekends. Another possible explanation of this phenomenon is based on the general state of the market participants. It was found that the mood of the people is better, more optimistic on Fridays and on days preceding holidays. On Mondays, the mood of the people in general tend to be more pessimistic, morose. Rendered in the investment area, these states generates reactions as: increasing quotations when the market is dominated by optimism (due to boost buying transactions) and decreasing quotations when market participants are dominated by pessimism (in this case they sell more).

#### **2.4. Another calendar anomalies.**

Besides already exposed calendar anomalies, there were also identified other effects, but at least for now those are remaining in the study of researchers in this field. Thus, according to an analysis company of stock market trends it seems that there is a anomaly on the returns obtained from investments on the stock market in the years ending with the digit "5" (<http://bigcharts.marketwatch.com/>, 2012) . At least apparently, the Dow Jones Industrial Average level seems that the years ending with the digit "5" bring positive returns to investors. For example: 2005, 1995, 1985. This notice is not valid for years divisible by 5. The yields include in the company analysis both the DJIA index value at the beginning and at the end of the year and also the dividends of listed companies which are taken in the calculation the DJIA.

A brokers adage vis-a-vis investment on stock exchanges, which is already famous, says: "Sell in May and go away". Like any saying, this was basically the result of many experiences from brokers, which showed that the period between November and April is characterized by significantly stronger increases than in other months of the year. November usually brings gains for stock market quotations, its beginning is often associated with Halloween (which takes place in late October). Investors can use this effect to achieve higher returns than the market average, so they will buy listed shares in November and will sell, according with the hypothesis, in May. Bouman and Jacobsen have studied this phenomenon which they called the effect of Halloween (Halloween Indicator) and showed that their hypothesis is confirmed for 36 of the 37 countries surveyed, and the market in which this phenomenon can

be observed best is the London market (Bouman & Jacobsen, 2002). This anomaly has been studied also by Maberly and Pierce in 2004, and the conclusion they reached was that the returns obtained from investments on the stock market in many states were mostly negative or smaller in any case, in the months between May and October comparing with the short-term interest rate (Maberly & Pierce, 2004). So the conclusion reached by Bouman and Jacobson's and also the conclusion of Maberly and Pierce, is in fact a contradiction of the theory of efficient markets, and till now the reasons for determining this phenomenon are unclear. Therefore remains space for further research in this area.

An interesting anomaly is at least that of Mark Twain, which bears his name - "Mark Twain Effect". He noted that the yields obtained in October, from the stock market investments are lower than in any other month, and that's why he said: "October is one of the most dangerous to speculate. The other are July, January, September, April, November, May, March, June, December, August and February". Mark Twain not only draws attention to the low yields that can be obtained in October, but from his conclusion, he draw attention to speculation in general - it is extremely risky at any time when is initiated. A proof that the above is true is that the biggest crisis of the world began in or around October: 1929, 1987 or 2008.

### **3. High-frequency traders**

Trading with so-called high-frequency traders involves the use of sophisticated technological tools and of trading algorithms for trading the financial securities, in an extremely fast way. This type of transaction is made using advanced computer programs, and that's why the open positions are held only for a few seconds or in some cases even less (a few milliseconds). With this method it can be made a lot of transactions in a short period of time. High-frequency traders do not keep open positions from one day to another, therefore all the transactions are intra-day. A huge focus in this type of trading is put on transaction processing speed.

The analysts of Advanced Trading have estimated that approximately 60-73% of the total value of transactions made on the stock exchanges in the United States was conducted by high-frequency traders ([www.advancedtrading.com](http://www.advancedtrading.com)) in 2009-2010, this percentage reached at about 50% in 2012.

In essence, the activity of high-frequency traders involves trading in bid and ask of a large volumes of contracts or securities, the profit which they rely on from a single transaction is very small. But the multiplier effect makes this activity to be very profitable, given that they may terminate thousands or even tens of thousands of transactions in seconds. Of course, the profitability of this activity depends primarily on trading algorithm used. Those who use these mechanisms are very careful about the optimization parameters of the trading program, many times the distance between the issuing server and the stock market server, is take into consideration. This is because, as the two are more physically closer, the cross-reactive response time is also smaller. Every second and millisecond in this system is very important.

#### **3.1. Flash Crash**

The day of 6 May 2010 is also known as "Flash Crash" or crash at 2:45 pm, when an incident has made the New York Stock Exchange and the Dow Jones Industrial Average to fall by nearly 1,000 points representing at the while about 9% of its value. This decline was the largest ever recorded in the evolution of DJIA during a single trading day.

Due to the debt crisis in Greece, 6 May was a day destined to massive decreases for most of the world stock markets. If until 2:30 DJIA fell by about 300 points, at 2:32 makes its presence felt in the market a high frequency trader (an algorithm programmed) which was scheduled to sell certain contracts. Due to its involvement and other such algorithms, the downward trend is increasing, so that at 2:41 DJIA had fallen 600 points. At 02:45:28 stock suspended from trading for five seconds the contracts covered by the first algorithm, so after 20 minutes of the resumption of trading, the 600 points were recovered.

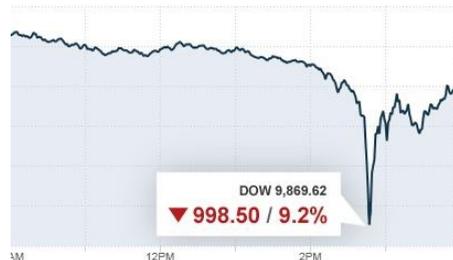

Figure 2. Flash Crash

High-frequency traders can cause enormous risks for the financial system. The consequences of such tradings have been observed in 6 May, when the Dow volatility has been excessive. This was the reason for that, many European countries have resisted approval of such practices. Angela Merkel, the German Chancellor has proposed a new legislation with clear control for high-frequency traders. The limitations were clearly exposed to german traders in the market, any infringements involving penalties and fines. The aim of the initiative was to limit the risks associated with the high-frequency trading.

#### 4. Conclusion

The existence of anomalies in financial instruments trading shows that financial markets are often inefficient or that those markets are some inconsistencies in the method of determining securities prices. The literature shows that such anomalies are attenuated over time or even disappear, also disappearing with them the profit opportunities of those who speculate trading financial securities based on those anomalies. By their nature, anomalies identified in the trading of financial instruments have a direct influence on prices, thus they are creating clear gain opportunities for speculators.

Anomalies in trading financial instruments are associated with the moments when the security prices deviates from the normal meaning, creating opportunities for those who identify them. These can be viewed from the perspective of time, in which case we can talk about calendar anomalies, in terms of interpretations of technical analysis, when we talk about technical anomalies, and in terms of performances given by the fundamental analysis, when we talk about fundamental anomalies.

Regarding the high frequency traders, we believe that it is required a special control for this type of automated trading because the destabilizing effects it generates in the market may be from the most serious.

## NEW DIMENSIONS OF BENEFITS AND RISKS TO BUSINESSES IN THE EUROPEAN UNION MARKET

**Dinu Ana-Maria, Rujan Ovidiu Adrian**

*The Faculty of International Business and Economics, "Dimitrie Cantemir" Christian University, Bucharest*

*The Faculty of International Business and Economics, The Bucharest University Of Economic Studies*

[anadinu13@yahoo.com](mailto:anadinu13@yahoo.com)

[ovrujan@yahoo.com](mailto:ovrujan@yahoo.com), [rujan.ovidiu@gmail.com](mailto:rujan.ovidiu@gmail.com)

**Abstract:** *The European Commission said that the economy of eurozone will decrease by 0.3% this year and will grow by 1.4% next year, with job cuts, shortage of investment and still tight lending conditions delaying the recovery. In the European Union as a whole, GDP expansion is projected at just 0.1% this year and 1.6% in 2014. The paper aims to identify the types of risks that a company faces when entering the European Union's market. Risk may be defined as an uncertain event that may have a negative effect on achieving objectives and risk management can be defined as the process that identifies analyses and accept or mitigate the uncertainty in business decision-making. Well designed and implemented, risk management programs are the source of competitive advantage for businesses in the European Union market and this way the operating costs can be reduced, quality and product reliability can be improved, staff productivity can increase. It is very important for any company to be aware of potential risks as this will help to assess, to prioritize and to protect against the risks that may arise. Some of the potential risk can destroy a business, while others can cause serious damage that can be costly and time consuming to repair. After the company have identified the risks, they must be prioritized in accordance with the companies assessment of their probability. The European Union expansion is ongoing and it is a major market place. Doing business on international level has always been about managing the unique risks which global markets pose. For many companies that intend to do business in Europe today, the risks are so varied and complicated that a risk management strategy is necessary and must be carefully tuned and revisited on a regular basis. There are many advantages when starting a business in the European Union. When participants and investors enter a new market should remain vigilant about risks.*

**Key words:** *risk, European Union, business, market, risk management.*

**JEL classification:** **G3**

### **Introduction**

In this moment of time, to maintain competitive advantage, companies are on a pursuit to expand the market share. Therefore, to achieve this purpose most companies have used globalization as a strategy.

Globalization refers to the elimination of barriers to trade, communication, and cultural exchange.

There are many reasons why a company ventures into foreign markets, such as:

- to spread business risk across a wider market base;
- to achieve/maintain core competences;

➤ to lower costs and enhance companies' competitiveness;  
to gain access to new customers- expanding into foreign markets offers potential for increased revenue, profit and long-term relationships and growth, and becomes an especially attractive option when a company's home market is mature.

***To enter the European Union market companies must consider the following objectives:***

- understanding the hindrances a firm might face while entering the EU market;
- studying the response towards the advent of the company in the new market;
- focusing on the customer taste and needs of the market;
- understanding the market strategies adopted by the top competitors;
- analyzing the EU market potential and market players.

In a study by the Economist Corporate Network, The Economist Intelligence Unit in cooperation with the company Marsh Romania, given the low level of knowledge of risk were developed four reports that highlight the challenges of risk management faced by the European companies. Each report covers a different field of risk business. All areas are particularly challenging in terms of aligning national legislation with the European Union legislation and the potential costs of failure or risk mismanagement have important effects.

**These four risk areas for European companies are:**

#### **Product liability and consumer protection**

European Union legislation on consumer protection and health includes 14 directives dealing with issues ranging from product liability to advertising. None of the new member states will benefit from transitional periods for implementing the legislation. According to those directives, producers are responsible for damages resulting from any aspect of the product. If it fails to be identified, each supplier of the product is responsible.

An EU directive on product safety came into force on 15 January 2004 and applies in countries that acceded on 1 May 2004 and acceding countries.

European Union legislation on food includes dedicated special regulations and control, how the labeling, additives and method of packing, practices local regulations differ greatly from the new member states.

#### **Health, safety and human resources**

The European *acquis* describe a very complex legal framework, consisting of 40 directives for all industries and services.

The judicial and administrative bodies shall establish national monitoring and recording complaints from staff. Employers' liability will rise to the EU member states. In a survey conducted in 2012 by the European Foundation for the Improvement of Living and Working Conditions found that there are major differences in this area between the EU states and accession countries. 40% of employees felt accession countries that are exposed to health risks and personal safety at work, compared with only 17% of EU employees who had the same opinion.

## Environment responsibility

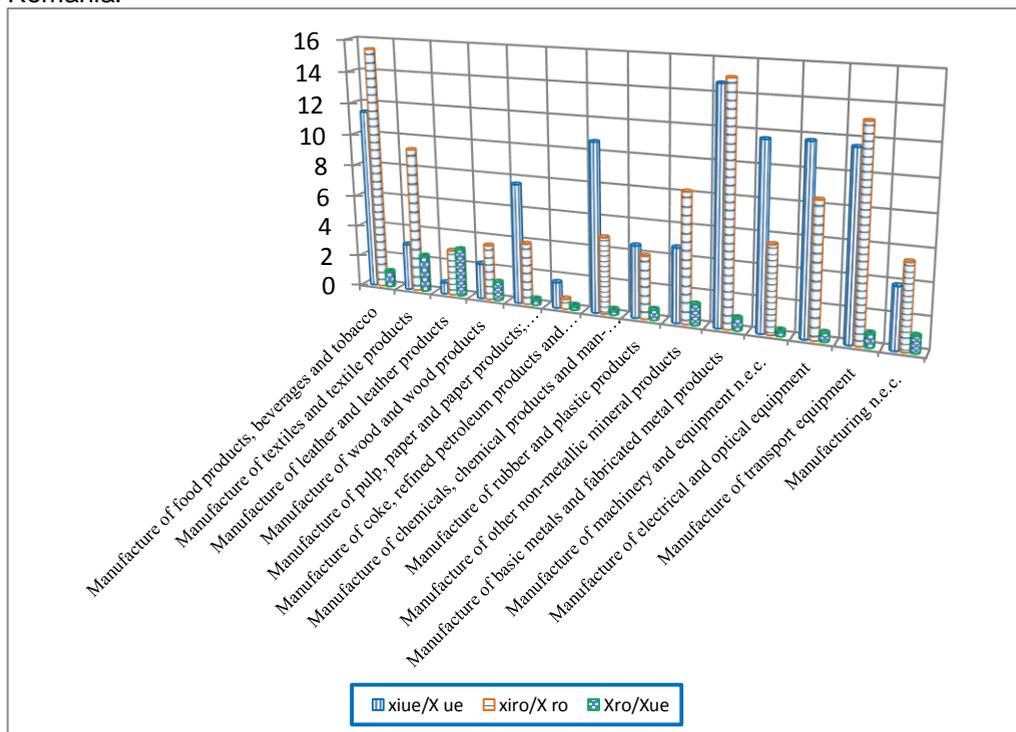

Adopting environmental acquis will require an investment estimated at 120 billion euros for the last two waves of accession countries.

In many cases, the acquis will require more stringent emission standards for hazardous waste management practices associated with handling and final disposal of all waste materials. Heavy industries such as chemical, energy and metals, will have to meet licensing requirements for pollution control as specified in the Directive on the prevention and control of pollution. Compliance with this directive will result in increased costs.

Environmental legislation is a goal of future changes. Regulatory changes will include "*Environmental Liability Directive*", which was adopted in the spring of 2004 and which, once implemented, could lead to an increase in the liability for contaminating activities and natural resource damages.

He also proposed a "*Directive on chemicals*", whose purpose will be to anticipate registration procedures and security assessments for companies that annually sells more than a ton of chemicals.

Romanian manufacturing production structure towards the EU industry is disadvantageous from the point of view of environmental pollution. The following figure shows a comparison of the position of various sectors in total manufacturing in Romania, the share of EU27 and Romania to the EU, the components of this industry, highlighting the fact that large polluting industries have a large share in Romania.

Comparison between Romania and the EU27 the value added and the share of manufacturing components in total and Romania share in EU27 in manufacturing industries in 2007

Source: EUROSTAT, Annual detailed enterprise statistics on manufacturing (NACE Rev.1.1 D), 06.03.2012

### **Managers' liability**

After several scandals during the global financial crisis in 2008 and 2010 that affected certain corporations, liability of directors for the company's shares began to attract the European Union' attention.

The action plan of European Union financial departments are seeking to create an EU-wide integrated capital market and to introduce International Financial Reporting Standards. The EU also plans to develop a guide of corporate governance. All this could lead to closer monitoring of shareholders and the directors' accomplishment of legislative tasks for the companies that are registered in Europe.

The failure to comply with EU legislation puts CEOs in vulnerable situations from litigation and penalties. Improved knowledge by consumers and employees on their rights will further strengthen this trend.

### **Risk management in Romanian companies**

Business was, is and will be exposed at risk. Risks are related to the complex nature of business. They cannot be completely eliminated but can be known, assumed and make them reduce adverse consequences. Lately, there are stands from which comes a warning in Romania: risk management should be on every manager's agenda.

Risk management is the natural consequence and the scope for other two essential steps: their *identification* and *hierarchy*, namely prioritizing their approach in the company. Hierarchy it is according both to frequency and impact severity on business. Follows the potential impact quantify of these risks on the business.

When a company has a clear picture of the risks to which they expose and they know the hierarchy, they decide which risks they want to manage. Risk management refers precisely the measures that a company has taken on the identified and hierarchical risks. Risk reduction measures should be the first step. It's the risks that a company decides to keep them and take them because they have the financial capacity that allows withstanding certain risks.

The next step would be the risks transfer that cannot be controlled by a third party who is actually called an insurance company. It is about the risks that the company decides that it cannot work those who cannot be assumed, because it would be a major impact on the business. The company transfers those risks to an insurance company against a takeover premium are the insurer risk price. The insurance benefit is that a company protects its business, protect their balance sheet and the impact cannot destabilize the company.

In Central and Eastern Europe and in Romania four risk categories occurs frequently:

- operational risks;
- strategic risks;
- financial risks;
- hazard risks.

*Strategic risks* may affect the company's activity and may lead to failure to achieve business objectives, *operational risks* are related to dependence on a company's processes, people and products, *hazard risks* are risks associated with natural disasters, accidental destruction of property or injury to employee termination

business, while *financial risks* may affect the company's results through exchange rate fluctuations and interest rate.

In Romania, 10% of companies that suffered a significant financial loss in recent years do not have yet a plan for crisis management.

Almost half of the companies in Central and Eastern Europe have not a clear strategy for incorporating risk management into their work. Most managers recognize that they have not implemented robust procedures in strategic risk management.

Companies from Romania and Central and Eastern Europe are not yet concerned with regulations coming into effect or have come into force upon accession to the European Union and its implications for company activities. To avoid possible sanctions, companies in the new member states should be familiar with an impressive volume of regulations and policies and ensure that their activities are conducted in accordance with them.

Economic and financial risk, the consequences of worrying economic environment, places Romania on the last place from 37 European countries<sup>1</sup>.

For Romania is important that political parties, government, democratic institutions have assumed leadership of the Romanian economy and society to establish and promote safe and effective economic structure, to develop policies in line with national interests.

## **Conclusions**

In time, increased competition may cause significant changes in the structure of markets in Europe. For the first time insurance buyers will have direct access to insurance products available in all EU member states. Externally, insurance providers will be able to attack the market share of local operations, without the need of efforts for the establishment and registration of new businesses.

Given this, international insurance companies will try to gain reputation locally, but could be cautious about the short and medium term strategies. In addition, do not have the local infrastructure to process large numbers of policyholders. In practice, it is assumed that foreign insurers are initially attracted by large corporations in the region, international presence, specific expertise and new insurance products will be the most attractive.

If companies want to make shelter from the risk of non-compliance and reduce the impact of future legislative changes, it is essential to understand and take account of the four risk areas identified in the study. But an effective risk management is not only to avoid disaster, but has the potential to create a competitive advantage. Companies that have an effective risk management are more attractive candidates for investments and acquisitions, and companies with a clear vision of the benefits arising from good risk management are more likely to generate sustainable development. With EU accession, a more efficient risk management may prove to be one of the most important benefits.

Activity of foreign direct investment has a positive impact on overall trade balance of Romania, concurring with 72.4% of the total Romanian export and import by 62.5%. It is known that the overall trade balance, recorded in chronically considerable deficits. Exports and imports foreign direct investment enterprises were significant

---

<sup>1</sup> www.marsh.com

share of the total ones. FDI enterprises trade balance registered deficits, but the situation is highly differentiated between branches.

Branches with trade surplus were: transportation, metallurgy, machinery and equipment, wood products, including furniture, textiles, clothing, leather goods, computers and other electronics, and the deficient - oil processing, chemicals , rubber and plastics and, contrary to expectations, food, beverages and tobacco, as shown in the annex.

#### Annex: Exports and imports of foreign direct investment enterprises 2010

## THE ANALYSIS OF THE REAL ESTATE INVESTMENTS IN THE CURRENT ECONOMIC ENVIRONMENT

**Hristea Anca Maria**

*The Department of Accounting, Audit and Economic Analysis, Faculty of Accounting and Management Information System, Academy of Economic Studies, Bucharest, Romania*

[amhristea@yahoo.com](mailto:amhristea@yahoo.com)

**Abstract:** *Real estate investments are one of the most attractive business opportunities in the context of the contemporary economy, generally marked by economic recession and especially by monetary and financial instability. Last years international reporting concluded that deepening the global economic crisis determined an increase of the real estate request, while despite all expectations one did not assist a crash of the prices. Economic reality showed that real estate assets value (buildings, land) kept proportions with economic reality over time. A comparison between stock exchange market and the real estate market shows that while an movables investor (investments in stocks, bonds or life insurance) might lose completely his initial investment, the investments in real estate assets, such as buildings, would keep their quality as goods and would also keep a value to better resist shocks and thus allowing an increase of the capital. When appreciating the value of an investment the first things to analyze are the return, liquidity and risk criteria, which are essential in real estate investments too. Stimulating real estate market must be not only a wish but also a reality of global economy, since it can correct many of the aggregated indicators of a country. Containing scientifically detached from economic practice, this article is addressed to readers with interests in real estate investment. The language is usually referred particularly to the qualitative side of the real estate market approach. The feasibility of the real estate investments is being conditioned by their capacity to generate important profits, on the background of the reduction of the duration of recovery of their value. The economic instability from the last couple of years has generated fears and failures but, paraphrasing Johann Wolfgang von Goethe, courage is a mixture of genius, magic and power that helps us succeed in everything we set our mind to. The investments on the real estate market usually have a long period of recovery, compared to the placements at the stock market or to the commercial business. The structure of investments in the field of real estate is complex and depends on several factors: the fiscal and financial policies of a country, elements that are specific to the constructions sector, the fluctuations of the real estate market, the development degree of a nation, the free circulation of people, the evolution of the exchange rate etc. The international statistics show that the real estate sector represents one of the most profitable businesses from the last two decades. Even now the real estate sector seems to be profitable, especially for the speculators, in the measure in which there are financial sources and enough information about the market.*

**Keywords:** *real estate investment; return of investment; investment liquidity; real estate investment risk; fair value; real estate market.*

## 1. Overall considerations

The start of global crisis generated major changes in the policies of economic entities and development strategies because the new context and the intervention factors in the market changed radically. The economic trends, that seemed unshaken before 2007-2008, started shaking until they had no value, at least in the present conditions when the vectors of the economic action are still confused.

Investment markets which had become during the last decade a tax haven for potential investors used to financial speculations became inert, weakly volatile, beyond the liquidity they had known so far. And so investors recently assuming financial risks and exponential increase benefits of financial transactions too, withdrew one by one from this scene leaving well-known stock exchanges in lethargy and with no hopes of quick recover. In economic theory there is proved that in conditions of a global crisis, the first deeply affected markets are the financial ones, especially the stock exchange markets, and they are the last to react to the economic increase. In other words, „first out, last in“. The stock exchange, a very attractive tax haven for experts, is the first link of an economic chain to feel the crisis shock and the last to react favorably and intensively to the economic increase of a state. The financial analysis indicate the fact that the cycles of the real estate market are in an inverted relationship with the evolution of the prices and they can extend on periods of time between two or three years and up to 20 years. The frequency of the two opposable markets – stock exchange and real estate – could be hardly balanced to reduce the difference between them. This is the fact influencing the interest of the investors to pass from one field of investment to another when it is necessary to increase the efficiency of the savings and returns. *In an empirical manner it was observed that the real estate investments have a sinusoidal trajectory, that is closely related to the **regularity** of the national economies, of the global economy in general, but the amplitude of the fluctuations is attenuated compared to the evolution of other economical segments. The financial analysis indicate the fact that the cycles of the real estate market are in an inverted relationship with the evolution of the prices and they can extend on periods of time between two or three years and up to 20 years.*

For decades we have been witnesses to the everlasting phenomenon of balancing between stock exchange and real estate investments. When the stock exchange has a downward, instability trend, the investors give up their “unreliable” shares in favour of real estate buildings.

Years before, the history of economic thinking pointed out that economy is inherently cyclic, meaning no matter the class of human society, it can't keep developing in one way (increase or decrease). In this context, the crisis should not be seen as a frightening phenomenon but as a state, a part of economy seen as a whole. Albert Einstein claimed it was good “not to ask things to change as long as we do the same. Crisis is the most blessed situation that can appear for countries and people, because it means progresses. Creativity is born of the necessity as day follows night. In crisis inventions, discoveries and big strategies are born. Without a crisis there is no duel, without a duel the life is a routine, a slow agony”.

What can be truer than the novelty elements which are always sources of surplus value and of distinction on the market, regardless of its phase: release, growth, maturity or decline?

## **2. Features of the real estate market**

The real estate market has many characteristic features and that imposes prudence and an analytic way of thinking from the investors:

- the real estate properties have a reduced liquidity degree because they involve complex procedures of transfer of the right of property and transactions with large amounts of money.
- the prices of the real estates and the decisions to buy or to sell are significantly influenced by the financing offers of the creditors, by the volume of the offered credits, by the financial costs, by the size of the deposit, by the duration of the reimbursement.
- the high value of the real estate properties takes time to analyse the financing manner and to check the reliability of the clients, and this leads sometimes to the missing of opportunities.
- through their nature, the information regarding some similar transactions are not available immediately, and for this reason the real estate market can be considered an imperfect one.
- the real estate assets have a long life-duration, that can be measured in centuries sometimes.
- from an accounting point of view the value of the lands cannot be damped, but the value of the buildings is damped in time.
- each real estate property is unique through its geographical location, its emplacement, usage value, dimension and financing form.
- the buying capacity of the investors has to be big, because the value of the real estate assets is high.
- the real estate market is characterized by important fluctuations of prices, due to their sensitivity to the establishing of the incomes, the unemployment rate, the size of the wages income, the evolution of the exchange rate, the interest of the investors.

The Russian researcher E.I. Tarasevici (2011) considers that the real estate market is an essential element of any national economy. In his papers he emphasized the belonging of the real estate assets to the category of merchandise and the close correlation that exists between the real estate market, the attraction of financial capital and the way of using the resources that are involved in this field.

Knowing the stage of the real estate market is a compulsory condition for the elaboration of the strategy regarding the real estate investments. An effective investment policy means the capitalization not only of the opportunities that exist on the market, but also a good evaluation of the investment objectives, and the adoption of some preventive measures of the potential threats generated by the installation of a negative dynamics of the market. Such an approach allows an evaluation that is well fundamented of the potential risks and the development of an investment strategy that is based on an optimum diversification.

## **3. Real estate - gold mine for investors solvable**

The real estate market became lately an interesting alternative for potential investors. Investing in buildings and slightly in land ensures the capital a good a long time protection against monetary erosion. Real estate investments are a very attractive business opportunity, based on the latest political, social, economical, legal

and financial evolutions as the reports and analyses in the filed show. For potential investors they might be the object of adopting the best strategies for the future.

Any investor knows that during crisis he can make the best investments. A Fata Morgana of real estate market, in a negative cycle, is hunting the minimum. Why? Because no one knows which is minimum and when it is reached.

Real estate investments have *many advantages* for potential investors because they are firstly long term patrimony elements, bringing extra incomes that contribute to meeting the needs, improving the quality of life long after the professional activity ends.

Even if risky, the decision of investment is supposed to have willingness and determination as triggering elements. Regardless the investor's level, experienced or beginner, he can immediately see the way to cleverly invest, with no previous important treasury. There are few persons affording to purchase a building and pay in cash, because the value of a building most often needs important savings and this is an impossible condition to most active people earning insufficient money to anticipate some major investments. Saving almost half of monthly income to open a bank deposit in order to purchase a house is a long time process, sometimes impossible and inefficient.

The financial credit is the solution to this problem. On condition of respecting the terms to pay debts back in time and totally, anyone could purchase a house and use it by means of loans.

At the end of credit period, the buyer is assured of owning the good and passing it to his descendants.

Selecting from specialized studies, we can point out the advantages of locative placements. "The stone", as an expert in real estate market said, is a respected investor of savings, the only one able to generate credit, despite all other investment forms (shares, bonds, life insurance etc.). By this loan we avoid the necessity to create own treasury to ensure the money for buying the building and we can set up gradually a solid patrimony as we pay back the debts. So a first advantage of real estate investments is to make up for the entire amount by long term credits (up to 30 years) and these credits are now in many countries more and more attractive due to low interests.

Despite all ups and downs, the real estate market has been growing for the past 15 years. Unlike a company current on stock exchange, when the investor might lose his initial investment once the capital market crashes, "the stone has a safety net". The advantage is that the capital assets are firstly goods unlike securities which are "a piece of paper" with a virtual value. When every thing goes well, the immovable asset serves its basic goal, to house one or more people.

An advantage of locative buildings bought on quality criteria, meaning "best location", in a good neighbourhood and connected to all facilities (public transportation, stores, schools, electricity, running water networks, sewerage system, resting centres) is that they will create value over time better resisting to possible market shocks, no matter what caused them.

Locative placements have also the advantage to provide a future income that might add up the pension income. At a current acquisition, the immovable assets generate a lower income, but as the credit is paid back, the building keeps its value.

Economic reality shows the buildings' prices in crisis don't drop as much as believed and this is the result of the exchange rate. Generally speaking, the buildings' price increases by every percent the national currency decreases as salaries and other

incomes are paid in national currency and this devaluation is equivalent to lowering the purchasing power and raising prices for houses. One conclusion is that the crisis deepening over the past years have determined a rise of prices in real estate investments not their crash.

Actually the buildings' value neither rises nor decreases but it is directly proportional to its economic utility. One condition to reduce real estate investment prices is to reduce the volume of the bank credits. In absolute amount, these can be reduced either by higher interests or by hardening the credit conditions. The lack of liquidities in the monetary market might lead to imbalance between supply and demand. Although the relation between the two market forces tends to change the price frequently, it is important to say that increasing real estate prices is merely speculative, mainly determined by the potential buyer who gives up on emotion: the express wish for a certain area, the attachment to a pre-seen building, insufficient information about the area prices, lack of time in making up a buying decision etc. Actually *the price must reflect the fair value*, based on impartial criteria.

#### **4. The features real estate investments**

Regardless of the geographical position of the investor, as it is well known, the value of the real estate investments as well as all investments must be estimated based on the following criteria:

- **Return on investment;**
- **Liquidity of the investment;**
- **Investment risk.**

**4.1. Return on investment**, generally on a placement is directly determined by the "health" of the market. In real estate sector a technical and economical analysis is necessary regarding: the placement type (houses, villas, offices, ongoing investment, land, woods etc.), the state of the asset (age, technical aspects, earthquake resistance, usage and the possibility to change it, access to facilities etc.) or geographical position (cities, capital, villages). As it is about long term investments, analyzing the future return involves anticipating the evolution of the market for a long time, an aspect hard to predict but of a real use.

When it is about preferences regarding the locative investments, the option is *old or new*? A motto worth following is: "A good investment is location". The answer to the previous question depends on the investor's interest and on the advantages created by one or another building.

International experience led to the following conclusions:

Investors direct to *new investments*, thanks to a sum of advantages, the most relevant are:

- National legislation directs to cheaper bank credits, with profitable interest rate for new buildings;
- Getting some important benefits in terms of quality, security, isolation or technical standards;
- Granting guarantees, in some countries up to two years, to cover the risks in case of damages when the investors move in the new building;
- Granting guarantees up to ten years to cover the risk of tightness and building resistance;

- Applying fiscal measures attractive to investors;
- Financial advantages: financial tax-free for 1-2 years, lower notarial expenses, the State grants facilities in case of renting the buildings etc.

In case of old locative buildings the advantages are:

- The neighbour's „karma”, the mirage of old times,
- Location downtown, next to historical sites, cultural and social traditional centres
- Reduce liaisons when negotiating the prices, because the owners themselves make the sale
- Attractive tax deductions,
- A significant number of investors interested in old vestiges,
- Satisfy different requests: wide rooms with high ceiling, small traditional cottages in villages with old history,
- Generate an important return of investment ,
- Lower prices compared to new buildings, although the accommodation conditions and fittings are comparable etc.

Regardless of the choice, *new or old*, the real estate investments compared to stock exchange market represent tangible assets, placed over time in the same location, with a value of usage and meant to self usage or to rent. In the opinion of specialists, the real estate assets are sure assets which even in the most tempestuous situations allow capitalizing and returning of capital. As shown previously in this paper the immovable buildings, if they abide by the legal settlement, they always return important positive benefits.

From an economical point of view, the global capitalization of an investment in this field comes from the summation of the capitalization rates that come from the renting of the real estate and of the valorization rate of the respective good, after the deduction of the expenses made with it.

The capitalization rate that is afferent to the renting is determined as a ratio between the value of the rent and the value of the good. This is bigger in the case of the so called “professional” buildings that have a lucrative destination, than in the case of the real estates that are inhabited or of the agricultural plots. Moreover, it is superior in the case of the areas that are situated in the central parts of the cities compared with the ones from the peripheral areas. Also there are significant differences between the urban and the rural areas.

**4.2. The liquidity of the investment** is another essential coordinate in establishing the area of interest of the future owner. If between the forces of the market the equilibrium is hard to reach, it is understood without saying that the real estate investment floats on a flat line. Even if the fast recuperation of the investment is not an immediate purpose for the investor, still it is a criterion for fundamental analysis. This happens because the value of the assets is determined by the rapport that exists between the demand and the offer that exist on the market. Thus on a market in which the offer exceeds the demand, the liquidity will not be obtained unless there is a great diminution of the price. In the field of the real estate investments, the capitalization can only be directly proportional with the liquidity.

So if it is necessary, it is very important the study of the “lever effect of the credit”, in other words the analysis of the principle of the multiplication of the sum that is brought by the investor as a contribution to the financing of the investment. For

example, at a contribution of the investor of 5% from the value of the financed project, the lever effect will be 20.

The efficiency of an investment depends on the correlation between the liquidity and its capitalization. According to the objective, the investment will have to define the type of capitalization sought: it is recommended to choose between a high renting rate (e.g.: offices) or a good potential to capitalize (e.g. buildings from the big cities that have good fittings and facilities). For a good appreciation of the efficiency it is suggested a fulfillment of the economical analysis with the determination of the financial and fiscal incidence of the selected variables, including the managing expenses, the maintenance, repairs, as well as the taxes and the customs that come with every chosen investment.

In order to answer the question “why is the real estate market considered to be a prosperous one?” we will have to make a synthesis of the previous arguments. The real estate investments, unlike other business, have a rare opportunity to fail, unlike other business where the prosperity can last for a long time or a really short one. Like in any other business, the economical periods that alternate, with positive amplitudes, followed by negative ones, influence the real estate market, but does not produce big fluctuations, so that the good offers last. There will always be a supplier that will meet a buyer. The statistical data prove that the current economical crisis there is a growth engine for the real estate market.

**4.3. The risk of the investment.** Like any other business, behind any investment there is a risk. The investment in the real estate properties imposes precaution measures that will reduce, when it is possible, to a minimum the risk of exposure. The risk of real estate investment aims the following components:

- The risk of gain that is determined by the failure to rent or by the nonpayment of the rent;
- The risk of capital that is related to a diminishing of the demands on the support market, given by the excess of constructions, by the modification of the behavior of the users, by the restrictive regulations;
- The risk of sub diversification of the owned patrimony, given by the necessary sum for the investment, its size being the condition to the access to this type of placement.

We must remember that the risks of the locative investments must be completely considered. As we have shown, the efficiency of the real estate investments is in a direct correlation with the investor’s possibilities to rent the property and to collect the income from the rents. In the conditions of the crisis, prudence must be manifested because in certain areas the finding of tenants is a problem, especially in the regions in which the economical activity is reduced. The prolonging of the periods of no rental coincides with a lack of capitalization of the investments. Another major risk is the fact that although the property is rented, the cashing of insufficient rent does not allow the investor to make the necessary maintenance work and repairs or the integral payment of the monthly installments that come with the loan. Other unwanted situations can be considered the nonpayment by the tenants of the debts from the holiday periods, their entrance into insolvency due to the lost of their jobs, the appearance of the conflicts between the tenants and the landlords that lead to financial and time loses to solve in a court of law the litigations, the appearance of damages and unexpected repairs.

It is vitally important the risk of general capital that is generated by the decay of the surroundings and the decrease of the value of the buildings or of the rents in the area, the appearance of natural risks, unforeseen in the area, the identification of the expropriation risks or the diminishing of the locative demand for various reasons, non known to the investor in the moment of purchasing the propriety.

The specialists recommend the investment in real estate assets with “capitalization” and not in the properties that are the most expensive on the market, because it is considered that in the next 25 years the main source of capitalization will be the revalorization of the property. The study of the profitability of the real estate investments is necessary and it needs prudence regarding their sustainability. For example the construction regulations evolve very rapidly and they tend towards energetic renovations of the buildings. In the moment of acquisition the investor has to integrate into the costs the expenses for the rehabilitation of the buildings and only then he can determine their real efficiency.

As we have shown above the dynamics of the real estate market is conditioned by the banking policies. The reduction in certain periods of the given credits is a real reason for the limitation of the real estate investments. This is due either to the increasing of the harshness of the banking institutions, through the tightening of the criteria for giving a loan, or though their rise though the increase of the interests.

In conclusion behind any investment there is an accumulation of risks. An unwanted risk is the losing of the investments due to different causes. When it is chosen a real estate investment, since the beginning there is a risk of losing it. For this reason, the risks must not be perceived as an obstacle in making the investment, but as a warning for the initiation of its beneficiaries in the good handling of them.

## **5. Conclusions and proposals**

The bibliographical sources that I studied and practical observations have lead me to the following conclusions:

- now the real estate market is the barometer of evaluating the well-being of any nation
- in the real estate field the equilibrium between demand and offer is more difficult to be reached and it is very perishable due to the large values that are vehiculated
- the dynamics of the real estate investments is conditioned by the fiscal, monetary and financial policies, as well as the degree of occupation of the active population
- the real estate investments depend on the real power to buy and on the development degree of the work market
- real estate investments generate benefits after long periods of time
- in many situations the real estate market is overrated, due to the subjective criteria of approaching the problematic content in this field.

The development of the real estate investments is a premision of the global development of the human kind. From this perspective I consider that it is necessary to have a coherence at the level of gouverment policies through the adoption of some transparent and durable laws, through the stimulation of financing and fiscal relaxation, that will support the real estate market and it will offer the bigger chances to the interested investors. Above all the risks the real estate market is a big enhancer of the rise of the national economy. Beyond the obvious benefices brought

in time to the investors, the real estate market is an influent environment for the PIB, a source of reduction of unemployment through the creation of jobs in constructions, a source of incomes for the banking institutions and not last, an important contributor to the state budget. It is no wonder that the newest statistics indicate in the last years an important dynamism of the real estate investors in the poorer areas of the Globe. The internationalization of the real estate investments is a good example regarding the new tendencies of the global businesses. But real estate markets in most countries are not as organized or efficient as markets for other, more liquid investment instruments. Individual properties are unique to themselves and not directly interchangeable, which presents a major challenge to an investor seeking to evaluate prices and investment opportunities. For this reason, locating properties in which to invest can involve substantial work and competition among investors to purchase individual properties may be highly variable depending on knowledge of availability. Information asymmetries are commonplace in real estate markets. This increases transactional risk, but also provides many opportunities for investors to obtain properties at bargain prices. Real estate entrepreneurs typically use a variety of appraisal techniques to determine the value of properties prior to purchase.

## CAN BUSINESS EDUCATION CHANGE MANAGEMENT PRACTICES IN NON-WESTERN SOCIETIES?

**Jim Finlay, Abdul-Nassar Kassar, Mark Neal**

<sup>1</sup>Marketing and Hospitality, Lebanese American University, Beirut, Lebanon

<sup>2</sup>Information Technology and Operations, Lebanese American University, Beirut, Lebanon

<sup>3</sup>London Business School, University of London, London, England

*dr.jimfinlay@gmail.com*

*abdulnassar.kassar@lau.edu.lb*

*markneal100@gmail.com*

**Abstract:** *The purpose of this study was to determine the degree to which students from an American-style Business School in Lebanon expect the managerial behaviors that they are taught in the classroom to actually be applied by managers in the Lebanese workplace. Broadly categorized as accountability, gender equity, religious tolerance, consultation and transparency, the authors found little indication that such expectations existed. Even when they could be identified such as with racial equality, their relative strength was so weak that they were barely above neutral on a 10-point scale. What was perhaps most troubling was that expectation for the elimination of bribery and corruption actually declined as students matriculated through the curriculum. At least for the time being, it appears that Lebanese business students do not anticipate encountering American-style management practices, which have formed the core of the Business courses, when they enter the workforce.*

**Keywords:** *Accountability, Equity, Tolerance, Consultation, Transparency, Hegemony*

JEL classification: M16

**Background:** The issue of globalization often centers on the concept of “hegemony” and can be traced to the writings of Antonio Gramsci (1971, 1975) regarding the ability of dominant powers to infuse their values into the cultures of developing countries. From a management point of view, the “chief instigator” in all of this seems to be “American style” business education and its proponents quickly argue that appropriate business practices can only enhance the economies of foreign countries if these societies would only accept the logic of the American mode of conduct (Mir, 2003; Grey, 2002, 2004). Of course, the influence of American-style business education is not restricted to the third world. As Julian Birkinshaw (2011), a Professor at the London Business School, noted in *Fortune Magazine*:

“Consider a few basic facts. At London Business School, one of the top B-schools outside North America, more than 90% of the faculty received their PhDs in North America. The same is essentially true at Insead (France), IESE (Barcelona), the Indian School of Business (Hyderabad), and CEIBS (Shanghai). The top management journals, from *Fortune* to *Harvard Business Review* to *Administrative Science Quarterly*, are all based in North America. The top management consultancies, from

McKinsey to BCG, Bain and Booz Allen, all have deep American roots. Management ideology is, in essence, the last bastion of American hegemony.”

**Business education goals and objectives:** In business education, this “benign approach” to hegemony is couched as “leadership” with the end-goal being to improve the way business is currently conducted in foreign societies. Yet there are those who argue that there is a hidden economic motive. According to Turnbull (2010) “the current model of business education preserves the status quo of twenty-first century capitalism and leaders appear to be powerless to act against a dominant ideology that reveres shareholder value above all else.”

Within the business school environment, American values are considered to be sacrosanct since they are backed up by statutory law and this is reflected by the faculty members’ tendencies to select instructional materials that are founded on the American management ideal. In fact, work place realities are given “short shrift” since the possibility of reverting to “pre-modern” approaches to leadership would be unthinkable (Kjonstad & Wilmott, 1995).

**Management from an Arab perspective:** Managerial approaches in the Gulf States arose from a unique set of cultural factors stemming from tribal influences and desert survival. Often portrayed as being at odds with “progressive” Western values, at least one study revealed that Muslim workers are more contented and productive in a company run by Muslims and based on Islamic ideals (Hashim, 2010). Branine and Pollard (2010, 718-21) have gone so far as to suggest a “utopian” vision of Arab leadership based on Islamic values based upon their contention that Islam provides the structure for its own unique management approach founded on the following Islamic principles: *Intention, Mindful of God, Kindness and care, Justice, Truthfulness, Conscious of self-improvement, Sincerity and Keeping promises, Consultation, and Patience.*

What is interesting is that if one did not know that these values were taken from the Quran, they could just as easily be viewed as prime examples of American ethical values. Branine and Pollard (2010) go on to argue that not only would multi-national corporations benefit from following these tenets, Arab countries would improve their ability to attract foreign investment.

**The Situation in Lebanon:** Often viewed as a microcosm of Arab and Western value systems, with roughly a 2:1 Muslim/Christian population, Lebanon serves as an ideal location to compare Middle Eastern and American approaches to management. With a culture that is deeply-rooted in “paternalistic” traditions, the Lebanese tend to view gender equality somewhat differently (ILO, 2004; Khalaf, 1993a, 1993b). Also placing it in opposition to Western values is Lebanon’s history of corruption. According to its 2012 report, Transparency International rated Lebanon at 30/100 placing the country 128<sup>th</sup> out of 176 nations and near the bottom of the Arab World. Obviously, such levels of corruption tend to undermine attempts to achieve “accountability” and “transparency”.

What many opponents of “Arab values” fail to realize is that Arab business leaders do not necessarily conform to Western stereotypes (Muna, 1980; Weir, 2001). Admittedly Lebanon has a high Power-Distance level (80) but this places them between Romania (90) and Bulgaria (70). Therefore to view the Arab style of

management as purely top-down is patently incorrect (Hofstede & Hofstede, 2005; Gerster & Day, 1994; Ronen, 1986). In fact, the Arab system is far more complex for its roots stem from “Arab tribal power” which evolved into the leadership/authority paradigm that Ali (1995) labeled “sheikocracy”. The sheik’s power was based on their family and tribal affiliations and by default, persons who were close to the leader shared in his power. This gave rise to the tradition of political patronage (known in the Arab world as *wasta*) in which members of the extended family of the sheik, along with close friends and associates were recognized as holding both power and authority (Hutchings & Weir, 2006; Abdalla, Maghrabi, & Raggad, 1995; Weir, 2001). The existence of “wasta” appointments often results in individuals being elevated to positions far above their level of competency making the Arab World a poster child for *The Peter Principle*. The primary difference between Laurence Peter’s theory (Peter and Hull 1972) and the “wasta-based” hierarchy is that the appointees start at this point to begin with! Because the underlings have no decision-making power, the success of such a structure is epitomized by technocratic divisions of labor and a strict adherence to established rules and regulations which on the surface is highly reminiscent of Weber’s vision of rational-legal authority (1947). This has given rise to an extremely bureaucratized structure with relatively high levels of uncertainty avoidance although Lebanon (68) is markedly lower than Romania (90) and Bulgaria (85)...

### **Hypothesis Development:**

**Progressive Values Embedded in American Business Education:** The authors elected to focus on five key value systems that form the foundation of modern business practices in the US. Broadly classified as accountability, consultation, equity, tolerance, and transparency, these values form the core of the AACSB-approved curriculum which treats them as sacrosanct and as such, not generally open to debate (Panitch & Ginden, 2004; Goodstein, 1981). Although business students are progressively immersed in these teachings and gradually become more accepting of them as individuals, they are also able to observe the “realities” of the society in which they live and the fact that “work place norms” often dictate that these values are often ignored.

**Accountability:** Giddens (1984, p.30) defined accountability as being “accountable for one’s activities is to explicate the reasons for them and to supply the normative grounds whereby they may be justified.” Viewed from this perspective, the expectation is that superiors will abide by existing rules and regulations when dealing with their subordinates in a fair and impartial manner. The authors drew the following null hypothesis in terms of *accountability*: *H<sup>1</sup>: “Overall, there will be no difference between the student groups in terms their belief that appropriate behaviors regarding equal treatment in regard to promotion and rewards will be adopted by Lebanese managers.”*

**Equity:** Stobart (2005, p.275) defined equity in the following way: “Equity is defined as a qualitative concern for what is just. This involves, but is not the same as, equality of opportunity and of outcome.” Certainly there is no more overriding concept that permeates the American business curriculum than equity in treatment of women and other minority groups. As a result, the authors drew an additional null hypothesis relating to gender equity: *H<sup>2</sup>: “Overall, there will be no difference between the student groups in terms their belief that appropriate behaviors regarding gender equity will be adopted by Lebanese managers.”*

What is far less clear from the literature is the extent to which the Lebanese society will be as accepting of the same equity issues when they relate to members of other races. Given that much of their exposure to other races is with “domestic workers” the authors drew an additional null hypothesis regarding racial equality:  $H^3$ : “Overall, there will be no difference between the student groups in terms their belief that appropriate behaviors regarding racial equity will be adopted by Lebanese managers.”

**Tolerance:** Rather than include religion under the umbrella of equity, the authors chose to view it as a tolerance issue. Crick (1971, p. 44) characterized tolerance as “the degree to which we accept things of which we disapprove” and it has become another commonly advanced ideal that is manifested in American management practices. Despite the negative publicity generated by fundamentalist groups within the Muslim faith, religious tolerance is considered to be an essential Islamic virtue (Kurtz, 2005; Asali, 1994). But one must remember that Lebanon is also a microcosm in which five religious groups have competing political ideologies. Although this inter-religious conflict reached a peak during Lebanon’s lengthy civil war, its effects are still felt in Lebanese politics today (Ghosn and Khoury, 2011). Since there is no clear line of demarcation between religion and politics in Lebanon, the authors drew the following null hypothesis regarding tolerance:  $H^4$ : “Overall, there will be no difference between the student groups in terms their belief that appropriate behaviors regarding religious tolerance will be adopted by Lebanese managers.”

**Consultation:** Yukl and Fu (1999, p. 220) expressed the following view of consultation. “Consultation is also a form of empowerment because it provides subordinates with influence over important decisions. Consultation provides an opportunity for subordinates to voice concerns about adverse consequences of a proposed change.” In the United States, it is accepted that leaders have an obligation to consult with their subordinates on important issues and to keep them informed of pending decisions that may affect their personal well-being. Traditionally, the Arab leadership style included an expectation that the Sheik would consult with the tribe when it came to their overall welfare (Neal, Finlay, & Tansey, 2005; Welsh and Raven, 2004). Therefore consultation, at least as American business programs define it, is not entirely inconsistent with Lebanese management practices which led the authors to draw the following null hypothesis:  $H^5$ : “Overall, there will be no difference between the student groups in terms their belief that appropriate behaviors regarding consultive approaches to management will be adopted by Lebanese managers.”

**Transparency:** Transparency International defines transparency “as the abuse of entrusted power for private gain. It hurts everyone who depends on the integrity of people in a position of authority.” The most apparent abuse of transparency in Lebanon can be seen in terms of the endemic levels of corruption which are rooted in the system of *baksheesh* payments that were fostered during four centuries of Ottoman rule (Cavico and Majaba, 2010). As a result, the authors drew their first null hypothesis regarding transparency:  $H^6$ : “Overall, there will be no difference between the student groups in terms of their belief that appropriate behaviors regarding keeping employees informed about decisions that can affect them will be adopted by Lebanese managers.”

The Arab tradition that while the leader was expected to consult with his tribe, his power meant that his were not open to scrutiny or challenge. This led the authors to

draw an additional null hypothesis regarding *transparency*:  $H^7$ : “Overall, there will be no difference between the student groups in terms their belief that appropriate behaviors regarding open and honest dealings with employees will be adopted by Lebanese managers.”

There is no question that Lebanon is viewed as one of the most corrupt countries in the Middle East and these practices have become viewed as just another cost of doing business. The existing levels of corruption in Lebanese society certainly place the country’s business practices at odds with American values. This led the authors to draw their final null hypothesis regarding the implementation of anti-corruption policies by Lebanese managers:  $H^8$ : “Overall, there will be no difference between the student groups in terms their belief that appropriate behaviors regarding bribery and corruption will be adopted by Lebanese managers.”

## **Research Methodology**

**Development of the Instrument:** The current study is an extension of the work done by Neal and Finlay (2008) regarding American hegemony in business education. Their initial study relied on statements regarding management ILT as indicators of the degree to which “modern” business practices were being accepted by students. The current investigation expanded on his methodology by refining the instrument to directly address eight keys approaches to managerial behavior. A summary of the eight questions relating to the criterion variables can be found in Appendix 1.

**Data Collection:** The second improvement was to create a means of tracking the growth of hegemonial acceptance among business students. While Neal and Finlay (2008) gathered information from senior-level students, the current inquiry broadened the sample to include students who were taking introductory and graduate courses. As the students progress though their major or into graduate study, these hegemonic values are continually emphasized. As a result of this “benign indoctrination”, American students are sensitized to these issues and adopt them as the only acceptable way for managers to behave. The question here is not whether Lebanese students have the same level of acceptance, but rather if they believe that they will encounter the same managerial behaviors when they enter the workplace.

**Statistical Analysis:** The authors first conducted a standard ANOVA with the data to isolate significant variations in the group responses then followed up this analysis by applying the Scheffe’ option to the significant variables since it guards against the occurrence of Type 1 error and the resulting likelihood that spurious significant relationships could be declared (Hair, Anderson & Tatham, 1995).

## **Analysis of the Data**

**Hypotheses arising from the criterion variables:** This project was designed to determine the extent to which the five hegemonic values are perceived as being extant in the Lebanese workplace. The statistical summary of the ANOVA analysis of the eight questions comprising these five categories is provided in Table 1 and reveal that only in terms of racial equality, keeping employees informed and bribery and corruption were there any differences between the expectations of the student groups.

**Table 1**  
**ANOVA Results**  
**A Comparison of Levels of Agreement with Appropriate Behaviors**  
**By Stage of Business Education**  
**N= 463, df = 461**

	F Value	Sig.
Hegemonic Managerial Behaviors		
Appropriate behaviors regarding promotion and reward structures	.830	n.s.
Appropriate behaviors regarding gender equality	2.128	n.s.
Appropriate behaviors regarding racial equality	11.580	.000
Appropriate behaviors regarding religious tolerance	.066	n.s.
Appropriate behaviors regarding consultative approaches to management	1.992	n.s.
Appropriate behaviors regarding keeping employees informed about decisions that can affect them	4.158	.016
Appropriate behaviors regarding open and honest dealings with employees	1.682	n.s.
Appropriate behaviors regarding bribery and corruption	3.800	.023

Since three significant differences were noted, the authors employed the Scheffe ranked means option to the mean responses from the three student groups (A = introductory; B = capstone; C= graduate) where significant differences were noted. Unfortunate, the results that are summarized in Table 2 do not show a clear trend among the groups in terms of their expectations.

**Table 2**  
**Scheffe Ranked Means Results**  
**A Comparison of Levels of Agreement with Appropriate Behaviors**  
**By Level of Student's Education**

Change Scores: Hegemonic Managerial Behavior	Means	Scheffe α = .05
Appropriate behaviors regarding racial equality	A = 4.92 B = 5.38 C = 6.14	A < C
Appropriate behaviors regarding keeping employees informed about decisions that can affect them	A = 5.14 C = 5.74 B = 5.81	A < B
Appropriate behaviors regarding bribery and corruption	C = 4.99 B = 5.57 A = 5.86	C < A

**Accountability:** The low mean ratings, which actually show a uniform level of disagreement that the concept of accountability will be implemented by Lebanese managers. When combined with a lack of statistical significance (A = 4.73; B = 4.92; C = 4.58) the authors were led to accept the null hypothesis (H<sup>1</sup>) and conclude that

students do not expect to enter a workplace in which equal reward structures are present.

**Equity:** While the means show that the students are progressively hopeful that gender equity will improve in what is essentially an Patriarchal society (A = 5.32; B = 5.60; C = 5.87) their low levels of expectation and lack of significant variation led the authors to accept the null hypothesis on gender equity ( $H^2$ ) and conclude that students do not expect to enter a gender-neutral workplace.

Quite unexpectedly, the expectation that racial equality would be present in the workplace actually rose at each subsequent course level with the students enrolled in introductory courses being significantly less likely to believe in racial equality implementation than graduate students (means: A, 4.92; B, 5.38; C, 6.14). The reason for this finding is unclear but there is a possibility that students who have actual work experience may be interacting with equally-qualified employees from other races. Given these findings, the authors rejected null hypothesis ( $H^3$ ) and concluded that graduate students are more likely to expect racial sensitivity in the workplace than students enrolled in core courses.

**Tolerance:** The mean ratings show uniformly low levels of expectation in regard to this issue (A = 5.27; B = 5.36; C = 5.26) thus supporting the authors' expectations and leading them to accept null hypothesis  $H^4$  and conclude that students do not expect to enter a work environment where religious tolerance is practiced.

**Consultation:** The mean values for consultive behavior suggest that levels of expectation (C = 5.69; B = 6.06; A = 6.16) actually declined as students reached the point when they would be applying for work and were statistically similar. This led the authors to accept hypothesis:  $H^5$  and conclude the students do not expect their future employers to follow the text-book approach to consultation.

**Transparency:** The authors were somewhat surprised when the data in Table 2 showed an increasing tendency for students (A = 5.14; C = 5.74; B = 5.81) to expect to receive critical information from employers. The means rose significantly from the core level to senior capstone courses and while dropping off slightly, were marginally significant at the graduate level as well. While the relatively low mean rating of 5.81 still indicates that students are undecided if such information will actually be provided., the levels of statistical significance led the authors to reject hypothesis  $H^6$  and conclude that by the time business students reach employability, they at least hope that Lebanese managers will provide information regarding decisions which may impact their professional lives.

Such was not the case when it came to open and honest dealings with employees. The means were consistently low (C = 5.19; A = 5.21; B = 5.56) and statistically similar leading the authors to accept hypothesis  $H^7$  and conclude that students who will soon be entering the workplace are under no illusion that their bosses will consistently deal with them in an open and forthright manner.

The one factor that concerned the authors most, given its consistently devastating impact on the Lebanese economy, was bribery and corruption. The ranked means show a steady and significant decline in expectations from the introductory to

graduate level at which point the subjects are essentially ambivalent to the problem (A = 5.86; B = 5.57; C = 4.99). This led the authors to reject hypothesis H<sup>8</sup> and conclude that as business students enter the workplace, they come to the realization that the corruption which has plagued their country is far from over.

### **Conclusions and Implications:**

The findings from this study, which focused on students at three important stages of their academic careers, showed somewhat mixed results. In terms of accountability, gender equity, religious tolerance, consultation, and open and honest dealings with employees the mean levels of expectation were insignificant. Furthermore, since the mean ratings generally ranging between 5 and 6 on the ten-point scale, this indicates that the subjects were generally undecided as to whether these practices would be implemented. This finding alone suggests that the attitudes that students expect their employers to have are essentially inconsistent with the “appropriate behaviors” that they have been taught.

Even in the case of racial equality, where the mean ratings were significant and consistently rose from the introductory level, the mean for graduate students was only 6.16 which on a Likert scale would constitute barely agree. The same was true for “keeping employees informed” which, although significantly different, ranged from 5.14 to 5.81 indicating at best an attitude of hopeful uncertainty. The one factor which educators in Lebanon are most hopeful is that business education will eventually bring an end to the endemic levels of corruption and the strangling effect it has on the Lebanese economy. While the authors found a significant difference in the expectancy levels, the reason behind his variance was disheartening. The levels of expectation fell from a high of 5.86 with students taking core courses to 4.99 at the graduate level. The implications of this are clear. While students may initially be somewhat hopeful that things will get better, by the time they enter the workforce it is painfully obvious that corruption continues to flourish.

Student work-place expectations are an important aspect of human resource management. They govern the way that new workers view both their managers and peers and the behaviors which they feel will be most likely to “get them ahead”. This study suggests that although Lebanese business students may gradually come to accept the American-style management approaches taught in their classes, they are under no illusion that anything will change for the better in the Lebanese workplace. So what does all this mean? To begin with educators have by no means been operating under the illusion that change in the Middle East will occur immediately. As is the case with all cultural advancements, the impact is at best, generational. But what this does tell us is that although we may make a change in the thought processes of our students regarding appropriate managerial behavior, the question remains as to whether the reality of the workplace will “trump” idealism and continue to mire Lebanon in the status quo. Given these findings, even the most optimistic among us is left to wonder.

# THE ROLE OF INDUSTRIAL PARKS IN ECONOMIC DEVELOPMENT

**Meşter Liana-Eugenia, Bugnar Nicoleta-Georgeta**

*University of Oradea, Faculty of Economic Sciences, Department of International Business, Oradea, Romania*

[lmester@uoradea.ro](mailto:lmester@uoradea.ro)

[nbugnar@uoradea.ro](mailto:nbugnar@uoradea.ro)

**Abstract:** *In an attempt to accelerate the process of reforming the economy, the central institutions focus on supporting the use of technology to modernize the industry that would lead to the diversification of activities and the achievement of sustainable industrial development. The imperfections of the market and of the institutional system hampers companies' access to information, knowledge, new technology and financing resulting in increased business risk and directly affecting the progress towards achieving development goals.*

*Industrial parks may be considered as a solution to overcome these flaws in the attempt to accelerate the economic development by attracting innovative businesses that can generate jobs, higher incomes and therefore more resources to institutions. They can exploit the local potential in supporting knowledge-based business development and outline an environment where companies can interact with other supporting knowledge suppliers thus facilitating business and local development.*

*The approach of the subject is theoretical starting from the need to support the economic activities by local social institutions fostering the access to information and technology and identifying some solutions that meet these needs - industrial parks. Even if industrial parks in Romania are still considered in draft form, some examples can be identified as functional and supporting the local development. Their functionality is given by the involvement of local authorities and the interest of the business environment in exploiting the economic potential of the region. The role of industrial parks in supporting the local development is measured in the number of new jobs created, the income received by local institutions by paying taxes and duties from firms benefiting from the infrastructure made available through their involvement in attracting investors; the more productive the industry and more efficient the production, the higher the company's results and therefore the benefits of local institutions.*

**Keywords:** industrial parks, economic development, productivity, efficiency

**JEL classification:** F21, F22

## 1. Introduction

In the context of an overall development strategy, industrial parks can be a solution for increasing the local competitiveness through what it provides - institutional framework, modern services in administration, financial consultancy, training, technical guidance, information services, shared facilities, research and own infrastructure designed to meet the needs of companies they gather by providing them with modern services for the business deployment and development. A concentration of a variety of activities and services to support the industry can influence investors' decision to switch to such a region. Successful industrial parks can therefore become centres of growth and innovation, supporting local

development and contributing to the development of the national economy.

## **2. Industrial parks - production efficiency - local productivity**

Industrial parks are an important development tool adopted by many industrialized countries (Håkansson and Johanson, 1993). The growth sustained by the technology used in the industrial park opens opportunities for creating new jobs, improving local productivity and maintaining a competitive environment in the respective country (Markusen et al, 1986). In addition, producers operating in the industrial park will get greater benefits at lower costs. The chance to obtain additional benefits by supporting local development and the opportunity to create new jobs along with the income growth will positively influence the local economic development (Castells and Hall, 1994). These changes, together with the concentration of investment in research and development will modify the industrial structure of the local region and will contribute to upgrading the quality of life.

*Productivity* is a competitiveness indicator and reflects the effectiveness of activities. The factors affecting productivity were identified (industrial structure, capital savings, technology of adaptability, quality of the workforce) and analyzed by many experts concerned with the achievement of relevant studies which have verified the practical extent to which these factors are specific to the local environment (Kim, 1997).

According to the theory, productivity is the relationship between inputs and outputs in the production process. The efficient transformation of inputs into outputs, thus stimulating productivity is important for a region to become competitive from an economic standpoint. This input-output transformation requires the use of classical production factors: land, labour, capital, as well as the use of neo-factors such as information and entrepreneurship; to improve the input-output ratio or productivity, the emphasis must be placed both on the quality and on the quantity of capital investment, labour, and the locations chosen for production (Kresl, 1995).

The development of industrial parks is an important factor for any economy to actively participate in the global economic system. Industrial parks are based on knowledge and rely on the intensive use of technology. They are representative for the regional economic development and led to a decisive effect of stabilizing the economic reforms in economy. The innovation capacity is the main source of competitiveness of a producer. Innovation stimulates economic growth and development and plays an important part in acquiring the producer's performance and also in attaining long-term competitiveness (Howells, 2002). Innovation is the main way for producers to maintain a competitive advantage and enter new markets. Therefore, the production efficiency is closely related to the innovation of the manufacturing process. The benefits of the local environmental regarding productivity are derived from the innovation capacity since the industrial park gathers different economic activities and is the place where technological innovation may occur. The higher the capital-labour ratio, the more used the advanced production technology and the higher the level of labour skills able to apply new technologies in the production processes and getting new goods. Consequently, the local productivity will increase along with the productivity of labour and capital factors (Kendrick, 1977).

When managed successfully, industrial parks can provide a favourable environment for the development of concentrated firms but also for the local development. When not properly managed, industrial parks will not be able to overcome some issues faced by concentrated companies and that will affect the local environment, such as

pollution. Many industrial parks operate in an unsustainable way due to the social and environmental problems caused by poor management. Operating industrial parks reflect a desire to meet these challenges.

The policy of public institutions must be geared towards the support of industrial parks offering the possibility of a sustainable future. The framework conditions for industrial parks differ among countries and within countries due to the local governing competences, the social, economic, cultural and environmental aspects of each region and of the local community.

### **3. Industrial parks in Romania**

Last year the Romanian industrial sector increased its turnover by 3.1% compared to 2011 and represented a quarter of the total weight of Romanian GDP, which demonstrates the growing interest for this solution of supporting the business environment. One more reason why expectations are directed towards developers who should approach industrial park projects delayed for several years due to economic and political stability.

The interest in industrial parks is also proved by the transactions of industrial areas: the areas traded in Bucharest count up to a total of 38,000 square meters, while in other regions of Romania the total industrial area traded in 2012 comes up to 32,000 square meters, out of which 24,000 square meters were direct transactions between owners and renters. Nationally, the total rental activity consisted of 22 transactions with an aggregate area of approximately 89,000 square meters, the average being 4,000 square meters.

The largest transaction in 2012 was the rental of an area of 15,000 square meters by a chain store, near Bucharest, followed by a company producing car spare parts that leased 14,000 square meters in the same region. Other large scale transactions were that of a company producing electronic components that took over 7,500 square meters in the western region and a commercial company that has leased 6,000 square meters near Bucharest.

Logistics and industrial projects outside Bucharest, due to end in 2013 and 2014, cover 144,000 square meters, plus 70,000 square meters to be found in the drafts because of the difficulty to obtain financing. In 2012, the stock of industrial areas in Bucharest and around increased by 2% to reach a total of 980,000 square meters and the total rental activity increased by 40% compared with the beginning of 2012, according to a report on the industrial market in Romania. The demand for industrial areas at the end of 2012 increased by 24% compared to the demand manifested at the beginning of 2012, and most transactions were concluded in the capital city, representing nearly 35% of total demand. The total area of industrial parks in Romania in 2012 was 2337 ha.

The development of industrial parks is an important issue for economy because of the large investments attracted in these areas. The pulse of the existing businesses is perceived by means of the profits or losses declared by the companies managing these perimeters. Thus, according to a classification drawn by the earnings reported by firms that manage parks in Romania, the most flourishing businesses are in Bucharest. A company that manages an industrial park in the capital city earned last year a net profit of 6,096,315 lei for a turnover of 23,261,083 lei. The second place in point of earnings among firms that manage the 48 industrial parks in Romania is held by an investor who had the courage to develop the largest private industrial park in the south-eastern Europe who can boast with a net profit of 4,250 .971 lei.

In 2012 almost 50% of the investments in the industrial sector were attracted to Bucharest while Romania's southern and western regions attracted 25% and 20% respectively out of the investments made; surprising or not, the port area attracted only 1% of the investment. By enlarging the industrial park around Bucharest 20,000 more square meters of industrial areas were expanded. Logistics operators were the most active in the local market, investing both in domestic infrastructure optimization, and in expanding storage capacity. In order to fulfil the future development plans, they turned to other regions with growth potential. Nationally, no significant changes were recorded in the rent value; depending on the area surface rented it fluctuated between a minimum of 3.75 EUR / square meters / month and a maximum of 4 euro / square meters / month.

Agriculture, tourism and energy were considered, one by one or altogether as possible saving solutions for the Romanian economy. These options can be considered long-term solutions (5-7 years). Assuming that the main concern of most people is providing for living, Romania needs a functional economic engine today. There may be solutions; it is difficult to translate them into reality, so that the results, even the short-term ones are delayed. "Industrial parks" are considered to be the most viable solution for obtaining immediate results.

A good example and a successful model is the industrial parks in Hungary (205 functional industrial parks, most of them reaching or being very close to maximum efficiency) due to the national strategy for supporting the activity of industrial parks and to the thoughtful policies that provide consistent facilities and which are supported by a well-designed infrastructure, lobbying, even at the government level. In Romania, the competence to grant the quality of industrial park belongs to the Ministry of Regional Development and Public Administration or government. Following the pattern of countries with economic experience - shared at the meetings held in the various cooperation projects, involving companies from different countries, the development regions of Romania have developed a sustainable development plan with special attention to industrial parks.

By including industrial parks in their development plans, public institutions try to become strongly aware of the need to focus on those actions that create competitive advantages at regional, national and European level, including here the construction of industrial parks.

Considering the fact that the industrial park is a limited area in which economic, research, manufacturing and services activities are being developed so as to grow and enhance the natural and human resources of the area, involving local authorities to improve the state of networking among institutions and the business community in supporting local economic and social development by setting up a managing company refers to:

- providing / performing the utilities and services necessary for the activities carried out in the industrial park;
- ensuring and guaranteeing non-discriminatorily the right to use on infrastructure and utilities, according to the contracts concluded with beneficiaries;
- repairing, maintaining, modernizing and developing, accordingly the infrastructure and utilities within the industrial park;
- ensuring the access to the industrial park area meant for common use;
- administering industrial park spaces and buildings;

- managing their own as well as the attracted financial sources, in accordance with the strategy for operation and development of the industrial park;
- enabling the selection of applications for admission of new businesses in the industrial park;
- attracting investors for the development of productive activities and services;
- develop operating strategy and industrial park development;
- providing support for domestic and international partnership development, business consulting, technology consulting;
- ensuring the collaboration with governments, public local and central administration authorities.

The interest shown by authorities by ensuring these conditions as well as the investors' interest in valuing the local potential will lead to achieving some results in favour of the local development:

- increasing the number of jobs;
- increasing the amount of foreign direct investment;
- creating and developing high technology industries;
- developing activities that ensure the hiring of highly qualified staff;
- increasing the capacity to meet the needs of the domestic market, to expand exports and reduce imports of industrial products;
- producing competitive goods and services for domestic and overseas markets;
- conducting activities in accordance with the regional development objectives.

The important role industrial parks play in supporting the economic development and modernization is acknowledged by the European Economic and Social Committee as well, which recommends a more focused and integrated approach geared towards their support and development, in particular within the crisis and post-crisis context, requiring a more comprehensive strategy to take advantage of the benefits these parks can bring for growth and competitiveness.

With the support of central institutions, the improvement of industrial parks was provided with commitment referring to minimum investment amount from companies that are worth millions of euro, regarding the good-performance guarantees, and the minimum number of new jobs created and minimum gross wages to be paid to employees.

This could be considered an important step in achieving progress compared to the situation of the early 2000s when the local authorities received from the Ministry of Public Works, Transport and Housing the approval for the construction of a number of industrial parks; the perspectives were clear and the visions bold: building industrial parks on thousands of acres, vertically and horizontally that could channel towards urban areas the plus-product benefits for companies and the pathways could emanate enormous quantities of finished products towards the country's customs gates.

Industrial parks were meant to be the source of material benefactions for the workforce whom, looking for jobs used to migrate to these urban areas, be they central or peripheral. After two years, lost from the sight of the public institutions, the industrial parks turned into ruins.

The new projects of industrial parks have attracted major electronics and automotive companies, thus outlining a certain manufacturers and services supplier profile,

since the investors in question were important companies from South Korea, Spain, but also Romanian entrepreneurs eager to be closer to beneficiary companies in the West. In periods of economic difficulties, tax incentives and benefits granted by locating their businesses here represent the most important issues for investors. The first issues to consider are undoubtedly the geographical landmarks, but infrastructure and professional training of the workforce count as well.

The main advantages of the Romanian industrial parks are of two types: tax and material benefits. The tax benefits derive from the Romanian legislation that states tax exemptions for a period of three years for all investors settled in the industrial parks, and a substantial reduction of the tax on buildings. In addition, it is the municipality that builds up, with its own resources, the entire infrastructure (roads, electricity, water, sewage, heating, and telecommunications). The managing company supports the companies settled in the park, linking investors and local public institutions. The investors can also benefit from the free information on aid schemes and funding resources from European funds. The industrial parks are of Greenfield type, thus the promoted tender does not only rely on a low cost for the land but also on a complete network of utilities: water supply and sewerage network, roads, public street lighting, telecommunication networks.

The activities of the companies concentrated in industrial parks in Romania are mainly in the fields of:

- manufacturing, with the possibility to concentrate on various leading industries;
- business prevailing in the financial, banking, consulting, design, research and development activities, as well as business management activities;
- distribution focused on goods storage and logistics activities;
- services, where the industries producing services prevail;
- in addition to the activities that prevail and confer the specialization of the industrial park, there is a number of related services that can be carried out in order to support the development of these activities of expertise: provision of utilities, cleaning and security, trade and catering services, hotel activities, accounting services, business support services, insurance and other similar activities or direct linked to them.

In times of economic crisis, the support for these investors has come neither from the state nor from local market outlets, but from across the border; jobs have been maintained throughout the previous year thanks to the fact that the production of the park was geared more towards exports. In order to support investment in the industrial park and to shorten the periods for obtaining approval or authorization documents, the managing company collaborates with the representatives of local authorities, thus speeding up the process of administrative assessment to obtain the specific documentation. The Strategy of the Industrial Park stipulates the existence of the services important for economic such as banking / insurance, courier, etc. activities within the perimeter of the park.

In 2006, in Romania there were 37 industrial parks where there were 426 companies functioning with over 10,000 employees. Of these, 23 were operational, the others being in various stages of development. In 2010, there were 50 industrial parks throughout the entire country, created on a 2001 government ordinance that establishes the facilities that the state provides for investors who come to these places. The most important facilities are downsizing local taxes or establishing an

annual rent under the market value. Industrial parks and cheap labour force in Romania attracted big businesses of the global market that operate activities in various fields, from manufacturing to services and trade as well as foreign direct investment of billions of euro.

**Table 1.** Indicators associated industrial parks (2012)

<b>Indicators</b>	<b>Value</b>
<b>number of industrial parks (total)</b>	52
<b>number of operational industrial parks</b>	39
total area of industrial parks – ha	2337
<b>firms settled in industrial parks</b>	783
<b>employees in industrial parks</b>	34541

**The ten largest industrial parks created by the state in the last eight years, that attracted billion euro foreign investments and created over 22,000 jobs in the economy, still have 30% of their surfaces unoccupied. Although new investment projects were frozen the engines of production keep on working, "saved by exports".**

Examples of "good practices" are few, but not entirely concentrated in the capital city area; the western and also the southern or central regions are considered attractive to investors due to the opportunities offered, cheaper labour force in some areas, more qualified in others, nevertheless anxious to ensure a decent living especially after the "working abroad" experience.

The other parks - regardless of the region in which they were created (even some in Bucharest) lack a clear vision and an effective national and international marketing service, which, for the circumstances given when investors - Romanian and foreign - are particularly careful with money management and choosing locations, affects the business environment and the market.

**Table 2.** The situation of industrial parks in Romania (July 2012)

#### **4. Conclusions**

Industrial parks represent a factor with certain influence on the economic growth. They create conditions conducive to attract foreign investors. In Romania, the industrial parks in areas where they are functional have a positive influence on revitalizing the business environment, on transferring the modern technologies, and on restructuring and modernizing the industry. The construction of industrial parks in Romania has generated new jobs. Most of the new jobs have been created around the capital city and in the country's western counties. In regions where newly created industrial parks do not exist, there is a poor economic situation and the unemployment rate is high, here we are talking about regions in eastern and south-

eastern Romania. Creating and developing industrial parks in Romania is a process in an incipient phase, but, certainly, this is a solution in attracting investment and supporting local development long-term.

## E.U. ADVANCEMENT WITHIN THE WORLD TRADE: AN OVERVIEW OF THE LAST YEARS

**Nedelescu-Ionescu Daniela, Rujan Ovidiu**

Faculty of International Business, University of Economic Studies Bucharest

[daniela.ionescu@vait.ro](mailto:daniela.ionescu@vait.ro)

[ovidiu.rujan@ase.ro](mailto:ovidiu.rujan@ase.ro)

**Abstract:** *The expansion of global trade gained considerable force in the last decade, force that generated many transformations and changes. These transformations represent stronger improvements than expected, when compared with the preceding years, even if the trade growth remained below the average rate recorded in the '90s. Some of the improvements are supposed to be consequences of free trade areas expansion. In this sense the present paper aims to observe if the free trade agreements increased the members' international trade and how much a stronger union perform comparing to a weaker one. It analyses the effects of total trade made by the members of the main five free trade agreements: EU, NAFTA, ASEAN, MERCOSUR, and ANDEAN PACT, between 2000 and 2010. In order to analyse the effects of the total trade made by the members of these unions, the authors used data collected from the WTO International Trade Statistics published in 2009 and 2011. For each one of the five unions was built a distinct chart which illustrates the variation of exports and imports during the analysed period of time, as well as the trends of these operations over these years. Comparing all these charts they concluded that EU trade significantly increased as more countries joined the group, in contrast to the other groups which maintained their level along the time. Moreover they have noted a gap between the exports and imports performed by EU and the ones performed by the other unions. EU commercial exchanges were by far superior to the ones of the other areas and, in the same time, the EU trade fluctuations are broader than the ones of the other areas. Perhaps in the next period of time the commercial exchanges of UE and NAFTA will enhance with these areas whose potential has not been fully harnessed. On the other hand, creating a large common market the EU - NAFTA will most certainly constitute a guarantee for global economic stability and sustained economic growth.*

**Keywords:** openness to trade; free trade agreements; expansion of global trade; EU enlargement; EU advancement;

**JEL classification:** F1

## Introduction

The benefits of the free trade have been observed and argued for the first time by Adam Smith in the paper *The Wealth of Nations*, and by David Ricardo in *The Theory of Comparative Advantage*. Ever since, the vast majority of economists have accepted that free trade among nations improves overall economic welfare.

Along time the free trade agreements have proved to be one of the best ways to open up foreign markets to the exporters. The reduction of trade barriers and the creation of a more stable and transparent trading and investment environment make it easier and cheaper for companies to export their products and services to trading partner markets. As a result, the expansion of global trade gained considerable force lately, force that generated many transformations and changes. These transformations and changes represent stronger improvements than expected, when compared with the preceding years, although trade growth remained below the average rate recorded in the '90s.

Therefore the authors bent on remaking to observe if the free trade agreements increased the members' international trade and how much a stronger union performed comparing to a weaker one. In this respect they analyzed the effects of total trade made by the members of the main five free trade agreements: EU, NAFTA, ASEAN, MERCOSUR, ANDEAN PACT, for a period of eleven years between 2000 and 2010.

## 1. Methodology

In order to analyse the effects of total trade made by the members of EU, NAFTA, ASEAN, MERCOSUR, and ANDEAN PACT, have been used data collected from the WTO International Trade Statistics published in 2009 and 2011.

The total exports and total imports of every union were selected for each year separately, to be used for various comparisons.

Table 1: Trade in goods under the trade agreements of selected regions 2000-2010

	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010
<b>EU ( EU-15, EU-25, EU-27 )</b>											
Total exports	2316260	2319485	2465660	2926460	3728965	4026185	4543785	5347055	5922905	4595455	5156605
Total imports	2404840	2361815	2462350	2946525	3807395	4165680	4760045	5613560	6301625	4748535	5368030
<b>NAFTA</b>											
Total exports	1224920	1147505	1106179	1162906	1319617	1475764	1664105	1840714	2035178	1602322	1964481
Total imports	1683550	1579510	1600816	1723110	2007871	2283357	2540553	2700837	2906801	2176718	2681889
<b>ASEAN</b>											
Total exports	432027	387618	407395	474777	568926	655965	769767	865443	989894	814025	1052146
Total imports	380674	347141	366802	411810	513764	603050	688449	775799	939344	727071	953082
<b>MERCOSUR</b>											
Total exports	84591	87816	88824	106098	135811	163990	190131	223763	278366	217239	281307
Total imports	89866	84203	62342	69111	95090	113910	139540	182838	257942	186310	266655
<b>ANDEAN</b>											
Total exports	26225	25266	25966	29991	38931	51449	64824	76652	94500	78518	99165
Total imports	24505	27221	28405	30621	36917	46335	56402	70712	93584	74398	96783

For each one of the five unions was built one distinct chart which illustrates the variation of exports and imports during the analysed period of time, as well as these operations trends over the years.

### 2.1. EU trade during 2000-2010

With the collapse of communism across central and Eastern Europe, EU gained new members. In 1995 three new countries joined EU, in 2004 ten, and in 2007 two more. Thus in the analyzed period of time, respectively the last years, the EU members increased from 15 to 27, their number becoming almost double. In the same time the EU has gone beyond a simple reduction of trade barriers among its members, by evolving towards a deeper economic integration.

Chart 1: EU – total exports and imports during 2000 - 2010

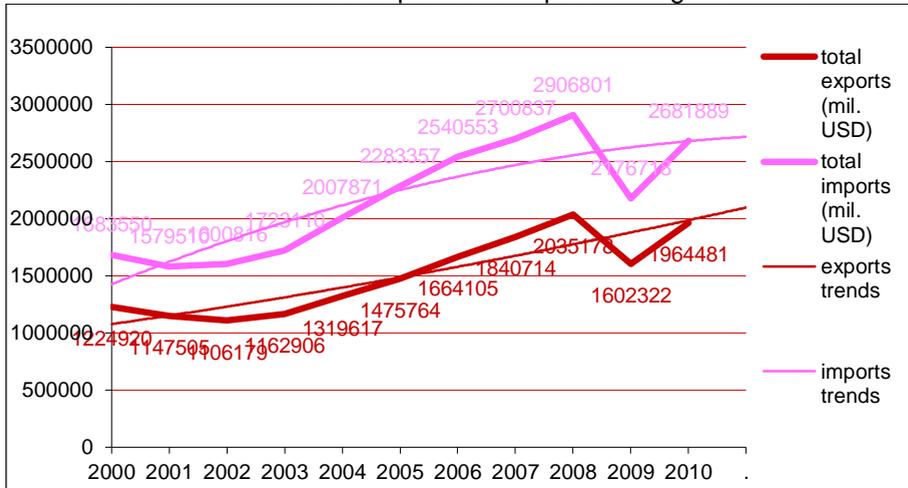

source of the data used for the chart: WTO International Trade Statistics 2009 & 2011

EU export and import evolved constantly during 2000-2010, as can be seen in the trends marked in the chart with thin lines. This happened mainly due to the fact that the number of countries in the EU increased significantly during this period.

## 2.2. NAFTA trade during 2000-2010

Chart 2 : NAFTA – total exports and imports during 2000 - 2010

source of the data used for the chart: WTO International Trade Statistics 2009 & 2011

NAFTA export and import trends during 2000-2010 were in increase, if even exports have registered a slower rate.

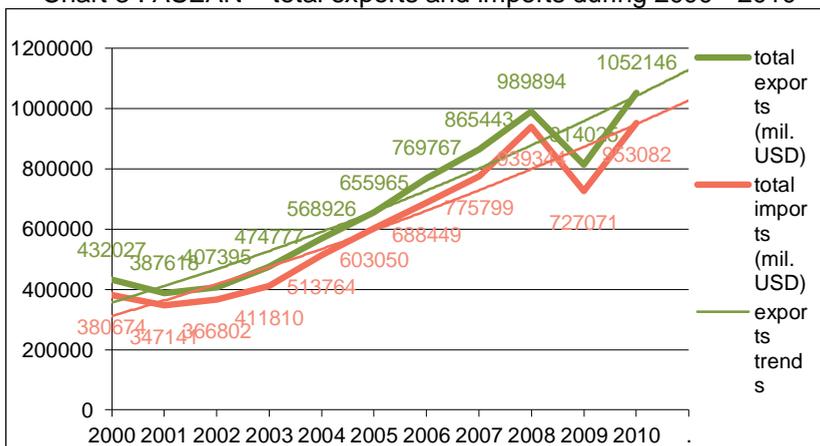

By comparison it can be seen that during this time the trade performed by NAFTA was lower than the EU one.

The fact that NAFTA was never supplemented by deeper forms of regional integration, social policies, or economic cooperation probably limited the benefits and exacerbated the costs.

It seems likely that U.S. imports from Mexico would have grown even faster and increased their share further between 2000 and 2010 in the absence of the huge jump in imports from China.

## 2.3. ASEAN trade during 2000-2010

Chart 3 : ASEAN – total exports and imports during 2000 - 2010

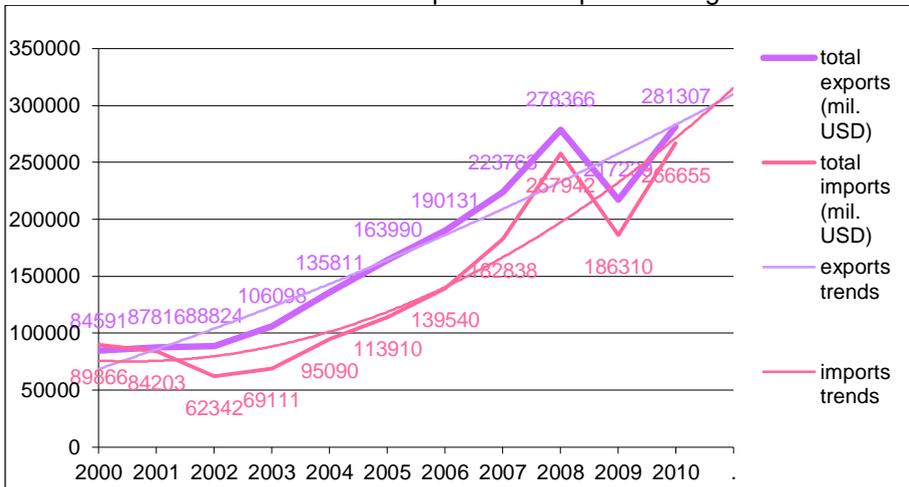

source of the data used for the chart: WTO International Trade Statistics 2009 & 2011

Also ASEAN exports and imports trends have been rising during this period of time. They had an analogue progress, if even the exports had a slightly higher growth rate. The trade evolution and trends are very similar to those of NAFTA.

## 2.4. MERCOSUR trade during 2000-2010

Chart 4 : MERCOSUR – total exports and imports during 2000 - 2010

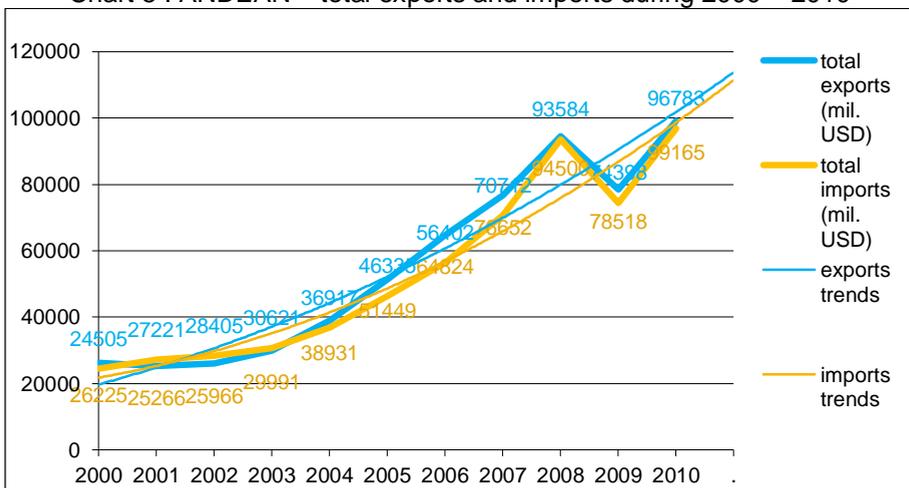

source of the data used for the chart: WTO International Trade Statistics 2009 & 2011

MERCOSUR exports and imports had a smoother growth during the observed time, but their trends have been steadily increasing. Comparing to the previous analysed union MERCOSUR's trade was a third of level.

## 2.5. ANDEAN trade during 2000-2010

Chart 5 : ANDEAN – total exports and imports during 2000 – 2010

source of the data used for the chart: WTO International Trade Statistics 2009 & 2011

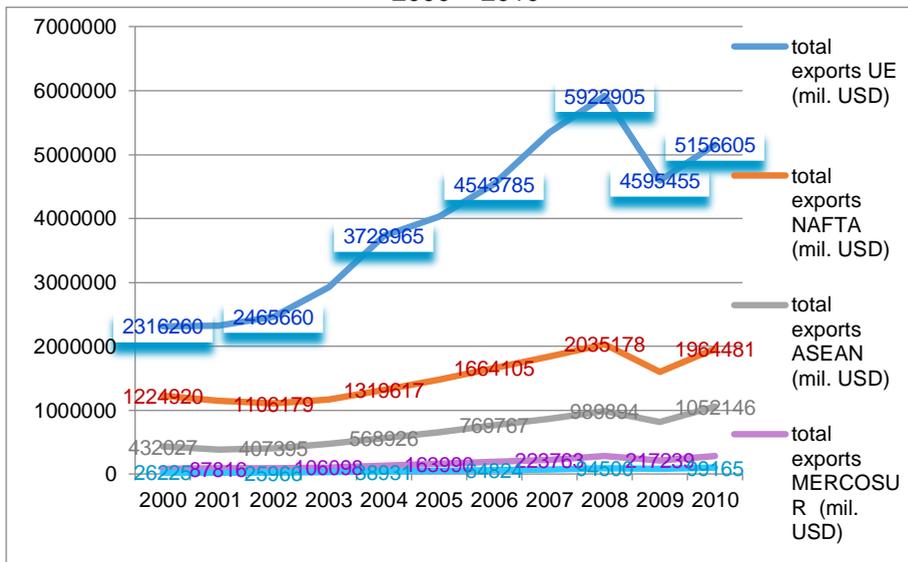

ANDEAN exports and imports trends during this time were in growth, they being at the same level all the time.

Trade liberalisation has been a prominent component of policy advice to developing countries for the last decades. Among the benefits claimed to spring from it, economic growth is probably the most important.

## 2.6. Exports and imports comparison

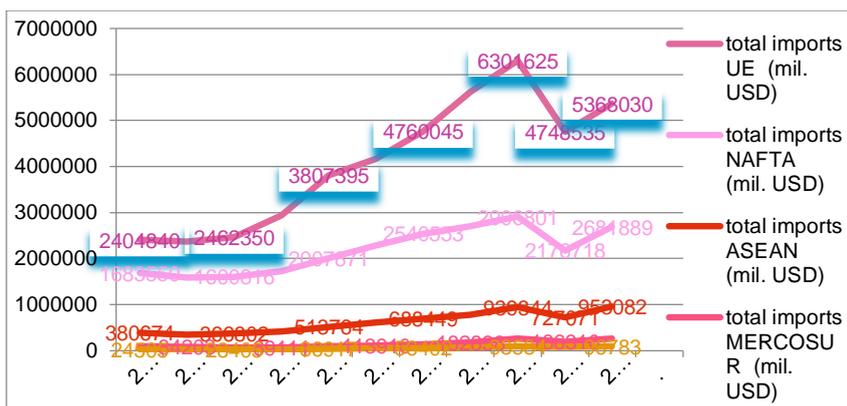

In order to see how much a stronger union performe comparing to a weaker one, we made separate charts for the exports and the imports performed by all five unions.

Chart 6 : Exports picture of UE, NAFTA, ASEAN, MERCOSUR, ANDEAN during 2000 – 2010

source of the data used for the chart: WTO International Trade Statistics 2009 & 2011

Chart 7 : Imports picture of UE, NAFTA, ASEAN, MERCOSUR, ANDEAN during 2000 – 2010

source of the data used for the chart: WTO International Trade Statistics 2009 & 2011

Comparing the Charts 6 and 7 can be observed that EU trade increased significantly once more countries joined the group, in contrast to the other groups which maintained their level.

Without any doubt was a gap between the exports and imports performed by EU and the ones performed by the other unions.

## 2. Results and conclusions

By comparing all the above graphs it can be seen that EU commercial exchanges are by far superior to the ones of the other areas and in the same time the EU trade fluctuations are broader than the ones of the other areas. This is also a consequence of the fact that the Union has expanded considerably in the analysed period.

EU trade increased considerably since more countries joined the group.

It is noted that both exports and imports of ASEAN, MERCOSUR and ANDEAN in 2010 exceeded the maximum level of the previous period from 2008.

Perhaps in the next period of time the commercial exchanges of UE and NAFTA will enhance with these areas whose potential has not been fully harnessed. On the other hand, creating a large common market the EU - NAFTA will most certainly constitute a guarantee for global economic stability and sustained economic growth.

## CONCEPTS AND METHODOLOGIES REGARDING THE IMPROVEMENT OF ROMANIAN FOREIGN TRADE (I)

**Negrea Adrian**

*Department of International Business, Faculty of Economic Sciences, University of Oradea, Romania*

[ngr\\_adrian@yahoo.com](mailto:ngr_adrian@yahoo.com)

**Abstract.** *The purpose of the current paper is to highlight possible engines that can boost Romanian foreign trade from a chronic deficit to a more balanced one. In the beginning, the main theories and models that tackle this subject will be presented. In this respect, the paper starts with Smith, Ricardo, Manoilescu and Heckscher-Ohlin, in order to see the historic thought of trade model development. Following these models, a more mathematical approach will be made, using a thorough analysis at the product level. All the computations will be based on the combined nomenclature with its XXII classes, being the most exact determinant of traded goods. This paper uses the statistical indicators of Michaely and Lafay, in order to determine the specialization effect of the Romanian classes for a period of twenty one years, starting with 1991 and ending in 2012. This is the point where former, current and future specialized engines of potential trade growth can be established. It is crucial for a country to determine its potential in an open international arena, in order to take the necessary steps to encourage or discourage productive or non-productive areas of certain industry branches. Based on the results and on the previous methodology, a mix of theory with solid mathematical analysis, will give the opportunity to draw up different sets of sustainable development formulas in order to obtain a higher concentration ratio regarding several classes from the combined nomenclature. For Romania to obtain higher gains from international trade, a more sustainable integration in the European Union, it has to stop its chronic balance of trade deficit. Looking at and analysing the potential development of a combined nomenclature class or classes, will help improving Romania's chronic deficit, offering a long term prospective of sustainable development, reducing its foreign debt, improving its balance of trade accounts, and transforming its import driven economy to a more competitive export oriented economy. Achieving these standards will ensure Romania's future development and accession to a more privileged seat in the European Union and in the international arena.*

### **The concept of absolute advantage**

The first who have tried to confute the mercantilist theory based on the concepts that the state policy should be focused on getting rich by all means possible, encouraging

only exports and discouraging imports were the classical economists. The most known ideas were stated by the British economist Adam Smith. The model of the English author is based on two states that produce only two goods, the so called 2X2 model. State specialization in the production of the good where it registers an absolute advantage and application to international trade in order to procure the other good, represents a win-win situation for both states.

The model in the figure below is relevant for the absolute advantage concept of Smith. According to Popescu (2001 and 2009), in Smith's model there is only country A and country B. Both countries produce "a" and "b" goods, the difference being that these goods are produced in different quantities. The labour hours necessary to produce both goods are also different. Based on Popescu (2001 and 2009) the following model will be created.

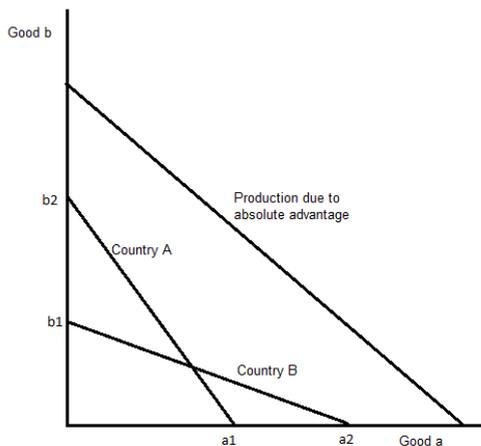

Table 1: The concept of absolute advantage expressed by the 2x2 model

Country / Good	Labour hours needed to produce goods before specialization			Labour hours needed to produce goods after specialization		
	a	b	Total	a	b	Total
A	60	100	160	160	0	160
B	90	70	160	0	160	160
Total	150	170	320	160	160	320
Country / Production	Total production before specialization			Total production after specialization		
A	500	500	1000	500 + 833 = 1333		1333
B	500	500	1000		500+642 = 1142	1142
TOTAL	1000	1000	2000	1333	1142	2475

Source: Own computations based on the 2x2 model of Popescu, G. (2001) *Modele de comerț internațional*, editura Corvin

As shown in the table, country A produces good "a" in 60 labour hours and good "b" in 100 labour hours. In return, country B produces good "a" in 90 labour hours and good "b" in 70 labour hours. Based on Smith's theory, the countries should focused on specialized production of that good where they register the highest internal comparative advantage

Figure 1: The concept of absolute advantage expressed by the 2x2 model

Source: Own computations based on the 2x2 model

The countries in the table should eliminate the production of those goods that consume too many labour hours. In the current case country A will eliminate the production of good "b" allocating the 100 hours for the additional production of good "a". Country B will register the same process eliminating the production of good "a" for the additional production of good "b".

If previously there was a total of 1000 units of each good produced and the total production was equivalent to 2000 units, after production specialization, the production of good "a" increases by 333 units and the production of good "b" with 142, leading to an increase of the overall production from 2000 to 2475 units. In this way, the countries will have to resort to the commercial trade between them, in order to benefit from the argumentation of the total production.

### The concept of comparative advantage

Based on Smith's model, the concept of comparative advantage has been developed and upgraded. The author of the new concept, David Ricardo, states that according to the specialization of the production presented and analysed in the model above, a positive effect for all the parts involved will be attained through international trade. Based on Ricardo, these commercial exchanges represent a positive effect game, a win-win type situation, where all the actors involved attain a certain gain. According to Popescu (2001), you can obtain a relative advantage if "in the exchange of the exported good you obtain a higher quantity of the imported good, better suited than it would have produced the imported good with the same amount of resources".

If we analyse Cerchez (2007), the idea of relative advantage occurs from the different internal opportunity costs. From here result the differences regarding the number of the labour force and the time needed to produce a certain good. The author develops the Ricardian model establishing the premise that there are multiple transactional goods noted from 1 to N, and the salary rate and the currency exchange are taken into consideration.

According to the author, the computation formula for determining the possibility condition of realising out the export process from one country is based on:

$$n_{1j}s_{1c} < n_{2j}s_2$$

Where

$n_{1j}$  = labour consumption / units produced, in country 1, for good  $j$ ;  
 $s_1$  = salary rate in country 1, expressed in international currency;  
 $c$  = currency exchange of country 2 currency, / country 1 currency;  
 $n_{2j}$  = labour consumption / units produced, in country 2, for good  $j$ ;  
 $s_2$  = salary rate in country 2, expressed in international currency;

Based on this concept it would be preferable the production of those goods obtained through to a higher relative consumption than of its partner, and obtaining other goods through international trade, whose production process would imply the use of even higher resources.

Comparative advantage indicators: Michaely Indicator

An indicator used in computing the comparative advantage is the one suggested by Michaely (1967), according to the formula:

$$MI_j^i = \left( x_j^i / \sum_{j=i}^N x_j^i - m_j^i / \sum_{j=1}^N m_j^i \right) \times 100$$

Where:  $x_j$  – represents the exports from section or product  $j$ ;  
 $m_j$  – represents the imports from section or product  $j$ .

The first part of the formula represents the percentage of the sector in the overall exports, and the next part represents the percentage of the sector in overall imports. According to Cohen (1969), the value of the indicator has to register values between -1 and 1, and in the case that neutral values are register they will be noted with 0.

Based on the previous formula corroborated with data from the National Institute of Statistics of Romania, data expressed in EUR, for the period 1991- 2012, based on the combined nomenclature, the results have been expressed in ANNEX 1, Table 2, where the Michaely indicator has been computed.

The results show that, for the following sections, Romania has registered a comparative advantage against the EU: wood and wood made articles, excluding furniture (section IX); textiles and textile articles (section XI); footwear, headgear, umbrellas and similar articles (section XII); base metals and articles of base metal (section XV); miscellaneous manufactured articles (section XX) especially furniture, lighting fittings and other similar articles, prefabricated buildings. As it is shown in the table, starting with 2009, Romania has lost its comparative advantage in the case of base metals and articles of base metal (section XV). For the rest of the sections from the combined nomenclature, Romania has registered a comparative disadvantage.

Based on these results, we can see that Romania has a comparative advantage in the sectors where intensive labour is needed. The severe part is that we import high technological goods, and suffering a comparative disadvantage in all technology intensive sectors. In other words, we sell cheap goods and import high priced goods from the developed countries, which lead to a chronic external trade balance deficit.

### Comparative advantage indicators: Lafay Indicator

When comparative advantages are analysed in the international trade flows, you can apply and utilise the Lafay indicator that can be calculated according to the formula:

$$LFI_j^i = 100 \cdot \left[ \frac{x_j^i - m_j^i}{x_j^i + m_j^i} - \frac{\sum_{j=1}^N (x_j^i - m_j^i)}{\sum_{j=1}^N (x_j^i + m_j^i)} \right] \cdot \frac{x_j^i + m_j^i}{\sum_{j=1}^N (x_j^i + m_j^i)}$$

Where:  $x_j$  – represents the exports from section or product  $j$ ;  
 $m_j$  – represents the imports from section or product  $j$ .

*According to Giurgiu (2008), "based on Lafay indicator, the comparative advantage of country  $l$  in the production of good  $j$  is majored by the deviation of the normalised balance of trade for good  $j$  from the normalised commercial balanced, multiplied by the share of trade (imports plus exports) of product  $j$  in total trade. By this, you can say that this indicator is complex and reflects the situation of the external trade balance by calculating the difference between the normalised trade balance and the global trade balance and probably this is the reason why it is often used in the analysis of the international trade"*

Continuing the reasoning of the study carried out by Giurgiu (2008) "the Lafay indicator allows the control over the distortions induced by the macroeconomic fluctuations and, from this perspective, it is superior to the indicator of the comparative advantage proposed by B. Balassa. While the comparative advantage is structural by definition, it is essential that the cyclical factors are eliminated, because they can affect the magnitude of short term trade fluctuations. The Lafay indicator takes into consideration these effects by calculating the differences between the normalized trade balance and the global trade balance."

When the time comes to choose between the two indicators, the decision can become extremely difficult. There are known in the international trade framework the different mutations taking place when it comes to international trade flows, of the production processes and intra-industry trade. According to Cherchez (2007) and Giurgiu (2008), at the level of the firm there are transformations regarding production, the firms frequently using processes of externalization or delocalization of production to different geographical regions.

Also, the production dispersion at the level of the entire planet contributes to production segmentation in different locations, breaking the final production from one country into multiple production processes of semi fabricated goods in diverse locations on the globe.

According to Giurgiu (2008) "the distortion introduced in the analyzing process depends on the level of these data aggregation because for an aggregate relative group of goods the intra-industry flow size becomes significant and any other evaluation of the performance of trade based only on exports becomes an absolute indicator."

Based on the previous formula corroborated with data from the National Institute of Statistics of Romania, data expressed in EUR, for the period 1991 until 2012, based on the combined nomenclature, the results have been expressed in ANNEX 1, Table no. 3, where the Lafay indicator has been computed.

The results are the same as for the Michaely indicator. Sections IX, XI, XII, XV and XX register the same trend. The comparative advantages regarding Romania's trade flows with the EU maintain a consistent progress for the above sections, only when it comes to section XV, Romania, starting with 2009, registers a comparative disadvantage.

If we observe closely, the comparative advantage of Romania does not derive from the sections with an intensive technology attribute like: machinery and mechanical appliances, electrical equipment, sound and image recorders and reproducers (section XVI); vehicles and associated transport equipment (section XVII); optical, photographic, cinematographic, medical or surgical instruments and apparatus and similar, clocks and watches, musical instruments, parts and accessories thereof (section XVIII).

The question that needs to be answered is what are the next actions of the Romanian government? Does it support those sections where the country registers a comparative advantage or will it support the development of companies in technology intensive business fields, in order to gain a comparative advantage there? This question will be very difficult to answer, requiring the strong collaboration between the private entities and the government, a collaboration that does not exist at this time.

### **The concept of utilizing the natural resources of a country**

The model developed by the Scandinavians Eli Heckscher and Bertil Ohlin presents the premise that all the countries should develop those goods where they register an abundance in production factors.

Based on the model developed by them, besides the idea of comparative advantage and the policy of trade liberalisation adopted from the classical economists, it is taken into consideration the intensity of production factors, more precisely, natural resources abundance.

Based on the analysis carried out by Popescu (2009), the concept tries to answer a series of questions regarding the rational allocation of resources, the factors that the terms of trade depend on, the results of international trade participations, the trade impact on the economic development.

According to Giurgiu (2008), the premises that the ideology structure is based on are the following:

- the factor necessity for the production of a good is different from a country to another;
- the natural resources that the countries are invested with are different from a country to another.

Based on these premises, the countries will have a comparative advantage in producing those goods that benefit from an abundance of production factors, either capital or labour. When trade exchanges are carried out, according to the H-O model, the phenomenon of adjusting the factor prices will take place, based on the demand and supply law (Samuelson and Nord House 2000) "The prices in the two regions have to equalize, like the water into communicating vessels has to reach the same level."

Both shorter and longer effects of international trade with goods and services will bring benefits to all participating countries. The comment made by Popescu (2009), based on the statement and ideas promoted by the H-O model, “countries left behind tend to catch up the developed countries”.

### **The concept of utilizing national labour**

One of the Romanian authors that express the frustration experienced by the agricultural countries against the industrial countries, between the interventionism and economic liberalisation, was Mihail Manoilescu. The author is aware that the goods from the industrialised countries are sold at much higher prices than agricultural goods, offering to the industrialists superior net revenues than for the agricultural produces. In other words, technology intensive goods are more valuable than labour intensive goods. According to his own quotation, Manoilescu (1986) : “industry in general has been built on the assumption that is possible to sell industrial goods so that the annual labour of an industrial worker to buy the labour of 10 farmers, this equivalence offers the key to understand the prosperity of western Europe in the 19<sup>th</sup> century”.

The model of improving the trade of under developed countries and developing countries, named by the author agricultural, was the development of industry and labour force specialization because “the wealth of all the nations and all the classes is based on their labour productivity”.

The author states that the highest net labour productivity per employee can become an indicator in determining the importance of the national economy branches. He defines the labour productivity as the division between the final value (Pt) and the amount of necessary work (At = workers \* time), according to the formula:

$$P = Pt / At$$

From which results the following:

$$Pt = P * At$$

Where:

P = labour productivity

Pt = final value

At = amount of necessary work

Industrial development accompanied by an increase of labour competitiveness in those technology intensive fields represents the key to success for every nation involved in international trade, according to Manoilescu.

The more an industrial branch obtains an output that implies the use of fewer resources, the more it will increase its degree of goods competitiveness and its probability of commercializing those goods in spite of fierce international competition. Manoilescu, being a Romanian author, argues the necessity of industrial production augmentation, the encouragement of developing new industrial branches, so that Romania cannot become a net importer, with a chronic external trade balance deficit, towards the developed countries with which it trades.

Following his assertion, the author denies the fact that through international trade every participating state wins. Manoilescu argues that only the developed states win

from international trade, having a better industrial production and labour productivity, the rest of the participating partners, poor developed and developing countries, registering external trade balance deficits. His theory is a win-lose situation for those countries that do not match a competitive industrial production and a specialized labour force.

## Conclusions

The main conclusions of this paper can be summarized as the following:

-all the competitive combined nomenclature sections are work intensive. In order to keep this edge, Romania needs to keep its minimum wage salary down, because if it will be raised, then the companies will lose their comparative advantage.

-based on the concepts of Manoilescu, Romania needs to encourage the sustainable development of those industries that need the best prepared workforce. In this scenario, the companies that are a part of the export production for the combined nomenclature sections XVI, XVII and XVIII should be encouraged by the state through fiscal, economical policies, and if it is possible, with the implication of the central bank to keep a high value for the euro currency.

-a combination with Manoilescu theory and the concept of utilizing the national resources, should be the key to success. Having almost all the natural resources that it needs, Romania from what it seems, doesn't produce high technology intensive goods. That being said, Romania prefers to sell its raw materials abroad, and in return, the country imports technology intensive goods at higher prices. This policy needs to change, because at this pace, in the long run, Romania's industry will cease to exist.

## CONCEPTS AND METHODOLOGIES REGARDING THE IMPROVEMENT OF ROMANIAN FOREIGN TRADE (II)

**Negrea Adrian**

*Department of International Business, Faculty of Economic Sciences, University of Oradea, Romania*

[ngr\\_adrian@yahoo.com](mailto:ngr_adrian@yahoo.com)

**Abstract:** *The aim of this paper is to emphasize the possible engines that can boost Romanian foreign trade from a chronic deficit to a more balanced one. In the beginning, we present the main theories and models that tackle the subject. In this matter, the paper starts with the analysis of neo-factors, Porter, the gravitational model, the input-output model, and the terms of trade in order to see the historic thought of trade model development. Following these models, a more mathematical approach is made, using a thorough analysis at the product level. All the computations are based on the combined nomenclature with its XXII classes, being the most exact determinant of traded goods. The paper uses statistic indexes as: Hirschman concentration index, elasticity coefficient, the degree of trade openness, in order to determine the specialization effect of the Romanian classes for a period of twenty one years, starting in 1991 and ending in 2012. This is the point where former, current and future specialized engines of potential trade growth can be established. It is crucial for a country to determine its potential in an open international arena, in order to take the necessary steps to encourage or discourage productive or non-productive areas of certain industry branches. Based on the results and on the previous methodology, a mix of theory with solid mathematical analyses, gives the opportunity to draw up different sets of sustainable development formulas in order to obtain a higher concentration ratio regarding several classes from the combined nomenclature. For Romania to obtain higher gains from international trade, a more sustainable integration in the European Union, it has to stop its chronic balance of trade deficit. Looking at and analysing the potential development of a combined nomenclature class or classes will help improving Romania's chronic deficit, offering a long term prospective of sustainable development, reducing its foreign debt, improving its balance of trade accounts, and transforming its import driven economy to a more competitive export oriented economy. Achieving these standards can ensure Romania's future growth and accession to a more privileged seat in the European Union and in the international arena.*

**Keywords:** *sustainable development, Hirschman concentration index, terms of trade, degree of trade openness, elasticity coefficient, combined nomenclature*

**JEL classification:** *F10, F19*

### **The neo-factor concept in the international trade**

The first author who emphasized the importance of neo-factors in the strong national economy framework was Michael Posner (1961). He highlighted the benefit of the correlation between investment in education, research and development with future outputs of intensive technology, goods and products, which are commercialized on the domestic and international market at a superior price.

In this way, according to Giurgiu (2008), the countries that made the first investments would hold an absolute advantage over the partner countries in the international trade. The tendency to imitate the newest products will make their initial advantages dissipate in time.

Following the same pattern, the product life cycle of Raymond Vernon (1966) makes it in the economic theory arena. According to the author, there are three stages in the life of new goods and products. In the first stage the new goods are produced in developed countries because there the markets are mature enough. In this stage the product can suffer different changes, this product not being a standardized one. According to Cerchez (2007) and Giurgiu (2008), the potential clients for these goods are only those consumers with high incomes.

In the second stage the product becomes standardized, the companies that produce it obtain economies of scale and economies from the efficiency curve, the price tends to get lower and exports to other developed countries start to rise. A tendency in the second stage targets the expansion of production facilities in the vicinity of the main markets, so that the product is no longer produced in the country of origin.

The last stage implies that the product has transformed from a pinion one into an ordinary one, being entirely produced in the poor developed and developing countries, the developed countries using imports in order to procure the products that they need.

According to Cerchez (2007), using the notion of technological gap, Vernon eliminated the premise of the H-O model, stating that the technology used in the production of goods process should be similar. In this equation besides the technological gap comes up the demand gap, because time passes until the demand is familiarized with the new product. From these 2 premises it results that the net gap is majored according to the author as a difference between the technological gap and the demand gap.

The same idea was developed by another theorist, Michael Krugman (1974) who states that the technological monopoly registered by innovative entities can suffer from the erosion of international transfer of technology.

The structure of human resource has a major significance in the thought of these authors, offering a possibility for development to those nations that invest in the preparation and training of this important work resource.

If countries want to hold their leader position they will have to make permanent investments in education, research and development so that the gap between them and the competing countries to be kept, or in a best case scenario to become even larger.

### **The concept of national competitive advantage**

One of the recent theories regarding international trade is the one based on Michael Porter's (1985) theory regarding the national competitive advantages, which combines the neo-factors with the concept of utilizing the natural resources and the labour work force. In the middle of his theory is the "Porters diamond", a structure

that combines a series of essential elements so that a country can impose its supremacy in international trade. His study focused on the industry of production of the first 10 most industrialized countries in the world.

The author identifies 4 essential attributes for a company to be able to register competitive advantages, these being the following: production factor endowments as human resources road rail aerial and sea port infrastructure, educational infrastructure, climate, natural resources, etc.

Porter takes into account the structure of industrial branches, analyzing the structure of related industries. The author states the fact that the industrial production cannot become a competitive one at the national and international level, unless there is interdependence between industrial activities at branch level. According to Giurgiu (2008), as for example, the United States' position is mentioned in the Information Technology sector, which has its core functions focused on semiconductors production, and the success of Switzerland in the pharmaceutical industry because it focuses is on developing its base, which is the chemical industry.

The third attribute's focus is on the conditions regarding demand formation. It is an important asset in Porter's view, arguing that a pretentious demand will force the company's policy into making permanent investments in research and development, so that their products will incorporate a higher technological degree and a superior quality. The last attribute emphasized by the author is the one referring to strategy, structure and competition among companies at national level. According to Porter, the steepest the competition among the companies at national level, the bigger the permanent investments in research and development will have to be in order to maintain or to gain new market share.

In this model there are 2 more factors represented by the economic policy and the interventionism of the government on one hand, and chance on the other hand. Usually, the state interventionism in economy can offer a better climate for sustainable development. Also the state policy regarding acquisitions can influence the progress of certain industry branches. The investment in education represents another method by which the state can influence the activity of companies and national economy level.

The concept of chance in Porter's theory highlights the advantages that a company can register the moment when it discovers new processes or resources through its research and development programs or by finding new natural resources unavailable at regional or international level, chances that can offer a competitive advantage over its main rivals.

### **Terms of trade index**

In order to hold a clear picture of the potential of the Romanian transports on the international markets the current paper emphasizes the analysis and interpretation of some index utilized in the measurement of international trade efficiency.

The first index used in the analysis of the international trade of one country with another or with an economic block, is the terms of trade. According to Stoian, Puiu, Motiu, (1973), the terms of trade represent "the relationship between the export and import prices respectively the buying power of one good in exchange to another, of some exported goods in exchange to the same imported goods, of export in its hole compare with the import".

According to Bari (2005), Cerchez (2007), Giurgiu (2008), this index can determine the value of necessary goods that need to be exported so that a country can import the same value of goods, according to the formula

$$I_{TT} = \frac{\text{export price index}}{\text{import price index}} \times 100$$

According to Genereux (2000), the formula states that the ratio between the export price index and the import price index records that  $ITS > 100\%$ , than it means the international trade offers an advantage to the exporting country because the value of the imports has reduced seems its base value. If from this ratio results that  $ITS < 100\%$ , the terms of trade of the analysed country suffers on behalf of international trade, because the country needs a supplementary quantity of exported goods in order to import the same quantity of goods from abroad.

According to Begu (1999), the terms of trade indices are derivatives from the statistical index that are subjected to the following premises:

- the economic functions are differently fulfilled by the export and import operations;
- the import operation implies the realisation of payments, while the export operation implies revenues.

Cerchez (2007) shows that the gross term of trade is calculated according to the formula as the share between the average export price index and the average import price index:

$$Irsb = \frac{I_{p_0}^E}{I_{p_0}^I} \cdot 100 = \frac{\frac{\sum q_1 p_{0E}}{\sum q_0 p_0}}{\frac{\sum q_1 p_{0I}}{\sum q_0 p_0}} \cdot 100$$

$Irsb$  - gross terms of trade;

$I_{p_0}^E$  - the average export price index base period;

$I_{p_0}^I$  - the average import price index base period;

$q_1$  - the quantity of goods exported or imported in the current period

$q_0$  - the quantity of goods exported or imported in the base period

$p_0$  export or import prices in the base period

The same author highlights the aspect according that the net terms of trade is calculated based on the formula as a ratio between the average export price index and the average import price index.

$$Irsn = \frac{I_{p_1}^E}{I_{p_1}^I} \cdot 100 = \frac{\frac{\sum q_1 p_{1E}}{\sum q_1 p_0}}{\frac{\sum q_1 p_{1I}}{\sum q_1 p_0}} \cdot 100$$

$Irsn$  - net term of trade

$I_{p_1}^E$  - the average export price index current period

$I_{p_1}^I$  - the average import price index current period

$p_1$  - export or import prices in the current period

$p_0$  - export or import prices in the base period

$q_1$  - the quantity of goods exported or imported in the current period

$q_0$  - the quantity of goods exported or imported in the base period

If we analyse the economic literature according to Cerchez (2007), Giurgiu (2008), the net terms of trade offers the best result when it majores the efficiency of a country's international trade relations. According to Giurgiu (2008), "it can be considered as an index of the external purchasing power, achieved by a nation through exports. If the important goods are in average more expensive than the exported goods, exchange conditions are unfavourable: in order to procure goods from abroad, the analysed country needs to produce and sell a higher number of goods and services".

Based on the studies carried out by Begu (1999), Cerchez (2007), Giurgiu (2008), there are other statistical indexes like the price scissors, which is used to determine the regression in the case of net terms of trade, based on the following formula:

$$FP = (1 - IRSN) \cdot 100$$

Also the authors analyse the impact, the revenue terms of trade also known as the index of the export purchasing power and the factor index of the terms of trade.

The index of the export purchasing power, according to the following formula, is obtained as the multiplayer between the average export price index and the net terms of trade:

$$Ivrs = (I_p^E \cdot Irsn) \cdot 100 = \frac{\sum q_1 p_1}{\sum q_1 p_0} \cdot \frac{\frac{\sum q_1 p_{1E}}{\sum q_1 p_0}}{\frac{\sum q_1 p_{1I}}{\sum q_1 p_0}} \cdot 100$$

Another index used in the measurement of the purchasing power is the factorial index of terms of trade, which according to the following formula represents the multiplier between the net terms of trade and the labour productivity index.

$$IFRS = IRSN \times I^W$$

When the time comes to analyse the results and we see that  $IFRS > 100\%$ , it is considered a positive evolution of the calculated index. According to the formula the results can be achieved due to a positive evolution of either terms, or only one of them, but with a more significant growth, so that the final result should be interpreted as a favour of the one.

Based on the information stipulated by Giurgiu (2008), in the factorial analysis of terms of trade you can utilise other equations such as: the degree of exports in the internal production and the degree of exports in the internal consumption. The first part you can obtain it as a share between total exports or those of the industrial branches and total internal production or industrial branches. The second part is obtained as the ratio between total exports or those of the industrial branches and total internal consumption or that of the industrial branches.

Table no.1: The evolution of the export / import price index and Romania's terms of trade during 2001-2011

Year	Export price index (Ipe)	Import price index (Ipi)	Annual rate Ipe	Annual rate Ipi	Net terms of trade (%)	Revenue index from the terms of trade
2001	97,16	97,51	-	-	99,64	96,81
2002	96,61	96,31	-0,56%	-1,23%	100,31	96,92
2003	101,84	102,92	5,41%	6,87%	98,94	100,76
2004	110,73	112,22	8,73%	9,03%	98,67	109,26
2005	120,58	122,39	8,89%	9,06%	98,52	118,79
2006	127,10	130,21	5,41%	6,39%	97,62	124,07
2007	135,89	138,27	6,91%	6,19%	98,28	133,55
2008	153,09	155,92	12,66%	12,76%	98,19	150,32
2009	146,62	145,41	-4,23%	-6,74%	100,84	147,85
2010	152,57	152,57	4,05%	4,93%	100,00	152,56
2011	167,37	170,35	9,70%	11,65%	98,25	164,45

Source: UNCTAD, <http://unctadstat.unctad.org/ReportFolders/reportFolders.aspx> and author's computations.

According to table no.1, the statistical data has been taken from UNCTAD, the base year, in computing the index, has been selected for the year 2000, and the reference

currency has been selected the dollar. According to the above data the net terms of trade registers a cyclical evolution, but mainly under the level of 100%. This fact indicates an unfavourable situation for our country. Only in the years 2002, 2009 and 2010 Romania registers values that exceed 100%, a fact that implies that our country in 8 out of the 11 analysed years has recorded an increase in the price of imports, being necessary to produce more in order to balance the result.

The evolution registered in the period 2009, 2010 is the result of only the economic crisis, which has significantly reduced the volume of imported goods in Romania. A positive evolution that needs to be mentioned is that of the export and import price index. Both of the indexes have registered an upward trend and not a disproportionate one.

According to Giurgiu (2008), after analysing the export and import price index, it has been noticed a decrease of export prices and an increase of import prices, a fact signed by an increase of external balance of trade deficit. In this analysis the base year that the index has been reported to was the year 1990.

### **The coverage degree index**

There are other indexes used in computing the efficiency of commercial flows like the coverage degree index. This index can offer important details regarding the analysis of international trade flows on which the government can adopt important majors in order to recover and improve its commercial policy.

In this case the coverage degree index is represented according to the formula by the ratio between the export value index and the import value index.

$$IGA = \frac{I^v(X)}{I^v(M)} = \frac{GA_{t_1}}{GA_{t_0}}$$

Based on these computations it can be observed the quarterly, semestral and annual evolutions of the coverage degree index. Achieving a balance between the imports and exports represents the primary goal of any commercial policy, the slippages from these goals having serious consequences at the level of the national economy.

When we try to compute the balance of the commercial flows you can use the formula of the relative coverage degree as a ratio between the exports value and imports value.

$$GA = \frac{\text{export value (FOB)}}{\text{import value (CIF)}} \times 100$$

After resolving the computations if it is obtained a result that points  $GA > 100\%$  it means a positive effect in the international trade flows, meaning that the country will register an external trade balance surplus. If the result shows that  $GA < 100\%$ , it means that the country will register an external trade balance deficit.

Table no.2: The evolution of the openness degree index and the coverage degree index of Romania during 1991-2011

Year	The openness degree index	Share of exports in the GDP	Share of imports in the GDP	External trade balance	The global coverage degree index	The coverage degree index with the EU
1991	30,47%	12,89%	17,58%	-4,69%	68,86%	93,52%
1992	41,81%	17,16%	24,65%	-7,49%	69,93%	59,34%
1993	37,14%	15,88%	21,26%	-5,38%	74,57%	68,12%
1994	28,40%	13,15%	15,25%	-2,10%	86,52%	95,31%
1995	39,63%	17,23%	22,40%	-5,17%	76,95%	83,05%
1996	44,10%	18,26%	25,84%	-7,58%	70,69%	81,95%
1997	49,48%	21,16%	28,32%	-7,16%	74,74%	81,19%
1998	42,54%	17,57%	24,97%	-7,40%	70,36%	78,78%
1999	50,31%	22,41%	27,90%	-5,49%	80,36%	89,06%
2000	68,73%	30,43%	38,30%	-7,87%	79,44%	89,61%
2001	74,93%	31,66%	43,27%	-11,61%	73,19%	86,31%
2002	73,26%	32,03%	41,23%	-9,20%	77,68%	89,40%
2003	61,87%	26,24%	35,63%	-9,39%	73,65%	86,41%
2004	59,90%	25,08%	34,82%	-9,74%	72,05%	80,93%
2005	55,62%	22,58%	33,04%	-10,46%	68,33%	74,28%
2006	63,12%	24,50%	38,62%	-14,12%	63,44%	64,63%
2007	71,72%	26,23%	45,49%	-19,26%	57,66%	58,30%
2008	65,67%	24,55%	41,12%	-16,57%	59,69%	60,79%
2009	58,48%	25,04%	33,44%	-8,40%	74,68%	75,87%
2010	70,20%	31,13%	39,07%	-7,94%	79,68%	79,34%
2011	73,11%	32,97%	40,14%	-7,17%	82,16%	80,43%

Source: author computations

The computations in table no 2 are based on the ratio between the value of Romanian exports in the FOB conditions and the external imports in the CIF conditions, all of them expressed in euro currency. As the table shows, both the global coverage degree and the EU coverage degree do not achieve 100%. In the entire analyzed period, the coverage degree registers values below 80%, a fact that is reflected in the external trade balance.

If until 2004 the situation of maintaining a relative good coverage degree of imports through exports destined to the European market had been achieved, starting with 2005 the situation has deteriorated due to the elimination of the external tariff duties due to the negotiated agreement signed by Romania at the accession treaty (1993).

These facts were corroborated with a flexible monetary policy that offered a lax access to liquidity. According to Giurgiu (2008) this situation influenced the population in purchasing electronic consumer goods, auto vehicles, a fact that has led to a decrease of the coverage degree from approximately 80% in 2004 to approximately 60% in 2008. Only when the financial crises made its presence felt, the consumption was dramatically reduced, having a direct impact on the coverage degree index, improving its situation.

## Conclusions

Year after year, Romania's situation regarding its chronic deficit is getting worse. From the data mentioned above, the coverage degree of imports through exports has never surpassed the barrier of 80%. This signifies that we import more than we export, and all the remaining percentage adds up at the national debt. For all the remaining percentage, Romania has borrowed money from foreign banks and international institutions. If this situation is maintained, the future generations of Romanians will have to pay the debt of this consumption boom.

The situation from 2009 and 2010 reflects the corrections suffered by a massive contraction of consumption. If this has happened only by the lack of consumption credits, by a decrease of revenues, than the Romanian government should think about introducing a progressive revenue tax in order to cut down the imports done by the people with high revenues.

Another situation that can be taken in consideration will be the reintroduction or upgrading non tariff barriers, especially excise duties, in order to diminish the 20% gap, so that the coverage degree of imports through exports should register a balanced result.

**Abstract:** *If in the first stages of the internalization of business, logistics had a minor influence in the international success of the company. In a globalized economy, strategy and the logistics costs are essential factors for competitiveness. Nowadays, logistics determines the place which a country or a company holds in the worldwide competitive hierarchy. The new Incoterms – 2010 – establish – in the field of commercial practices this reality: performance is now assessed in global terms (not national), competition is global, not international. Ultimately, the new Incoterms encourage/stimulate the orientation of firms towards increasing competitiveness by employing an appropriate logistics strategy; the degree to which firms will manage – as quickly as possible – to be integrated in this new trend will also be the measure of their competitive capacity in the newly emerged context. The category of global firms should not include just the large transnational corporations, but also the medium and small enterprises that operate exclusively or mainly on the global market. Within this plan there can be created and developed competitive advantages which are primarily based on the reaction speed to the changes in progress, the capacity to adapt to new things and the availability for intercultural communication. These last conditions represent characteristics of the Romanian business approach.*

**Keywords:** *global logistics; competitiveness; incoterms; international business*

**JEL classification:** *F59, L81, F23*

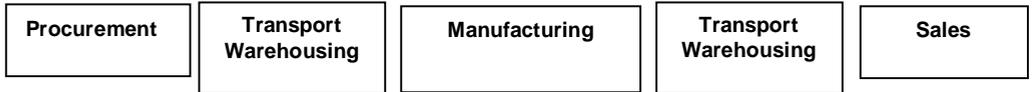

### **1. The development of logistics – from international to global**

The recent development of logistics marks the path from internationalization towards globalization in the world economy. If in the beginning logistics had only a minor influence in the international success of the company, gradually it became one of the major factors ensuring the latter's competitiveness at a global scale.

The first stage is that of the transition from the "international transports" approach of the process of physical merchandise delivery to the concept and strategy of international logistics. If in the 70's the main commercial powers (the advanced economies, corporations) were preoccupied with increasing the efficiency of the different logistics components –ensuring the necessary raw materials, handling the merchandise, storing it, packaging it, and above all transporting it – in the 80's the emphasis is on configuring and optimizing the logistics flows and on the integration and coordination of activities related to procurement, production and distribution.

With these objectives in mind, primarily beginning with the 1980's, many firms started to establish logistics departments or began to work with companies specializing in this field, and subcontracting all logistical activities to the latter (see Figure 1).

**1970: Classical Logistics**

**1980 : Logistics as a cross-divisional function**

**Figure 1 : Logistics - the first stage**

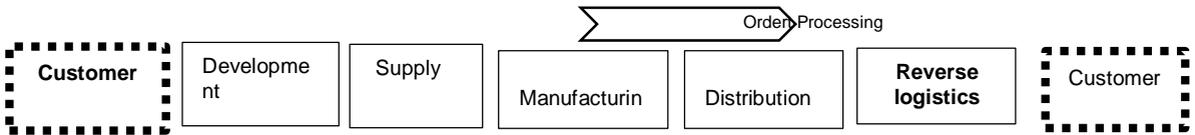

Source : Source : Baumgarten, H. , Beyer, J. and Stommel, H. (2004),

The second stage developed in the 1990's, along with the breakthroughs in the IT field, which allowed control over the flows of information in the supply chain. Nowadays a more holistic approach is being pursued, where the emphasis is on the integration of merchandise and information flows with the aim of optimizing the entire supply chain.

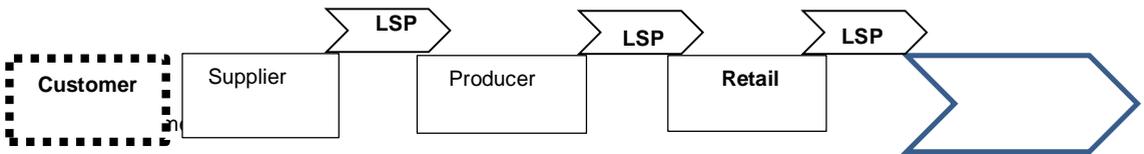

In international business the supply chain management approach regards the supply chain as constituting a continual process, starting from the imports order and finishing with the delivery of the merchandise and payment of price. As such, a systemic approach is needed, implying a single planning of resources for the entire company and a global optimization of activities. An approach of this kind can be employed within a single entity, but it can also be applied to a group of more entities, constituting what is called a virtual enterprise or an extended enterprise (the supplier of the supplier> the supplier> the enterprise> the client> the client's client).

Thus, logistics is becoming a major component in the business strategy of companies, allowing the attainment of competitive advantages by capitalizing on the services/information component – formalities, documents, security, etc.-international transactions. (see Figure 2)

**1990 : Phase of functional integration**  
**Logistics integrates functions to process chain**

**1990 : Phase of multidisciplinary integration**  
**b. Logistics integrates enterprises into value chains**

**Figure 2 : Logistics - the second stage**

Source : Baumgarten, H. , Beyer, J. and Stommel, H. (2004),

The beginning of the 2000's brought about a new stage: the flows of goods and information are planned and controlled not only within departments at the company level, but also at the supplier-client level. This integration is possible by implementing the Supply Chain Management based on ERP systems, systems connected through EDI links (Electronic Data Interchange), APS (Advanced Planning Systems), which have allowed this development. On the basis of these, presently, the process of integrating the logistical components is realized at the global level, relying on an integrated global network.

## **2. Logistics and Competitiveness**

In a globalized economy, logistics and the logistics costs are essential factors for competitiveness; furthermore, in the production/commercialization activities, the highest share is that belonging to the costs of logistics activities. The logistics costs account for 5-20% of the total costs in commercial or manufacturing enterprises.

Logistics also determine the position a country holds in the worldwide competitive hierarchy. In what concerns our country, if we analyze the data pertaining to two important reports relating to competitiveness, we arrive to some interesting conclusions.

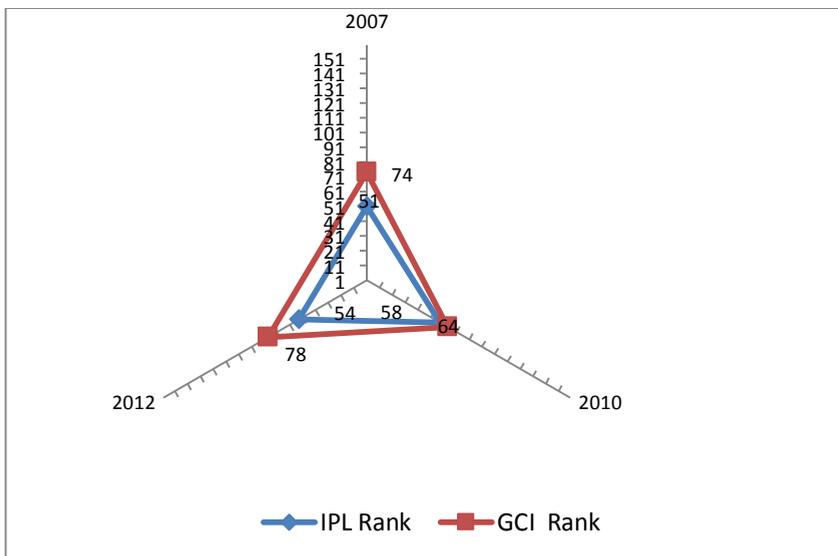

In the Rapport „Connecting to Compete” an index of logistics performance is computed, taking into consideration the following criteria: customs, infrastructure, international shipments, logistics competence, tracking & tracing, timeliness.

In the year 2007 the first edition of the rapport was issued and a Logistics Performance Index was computed for Romania, resulting in a value of 2.91 points, ranking it on the 51<sup>st</sup> place among 150 states; Romania took the 35<sup>th</sup> spot for cross border transportation but only qualified for a mere 123<sup>th</sup> spot when it came to internal

costs. For infrastructure the overall world ranking was 50 and for criteria such as the logistic competence – the 52<sup>nd</sup> place – customs activity and tracking deliveries (the 56<sup>th</sup> for both criteria).

Along costs, the score for competitive advantages (ranked 66<sup>th</sup>) pulled down the list the final score. It must be specified that countries where costs are high risk losing the chance of capitalizing on the opportunities of globalization. In its second edition –in the year 2010- the Rapport’s Logistics Performance Index evaluates Romania as having a score of 2.84, placing it on the 58<sup>th</sup> spot among a total of 155 states. In the year 2012, Romania’s LPI was 3, a value ranking it on the 54<sup>th</sup> place.

On the other hand, in the Global Competitiveness Report, the position held by Romania in the years mentioned above was as follows: in the 2010, Romania’s position in the global ranking of economic competitiveness has improved, a value ranking 67<sup>th</sup>. Last year, our country occupied, according to WEF, 78<sup>th</sup>, down one place to 77<sup>th</sup> position occupied last year. The overall score obtained by Romania was 4.07 points on a scale of one to seven, less than a score of 4.08 points in the last year. (see Figure 3)

**Figure 3: Romania GCI vs Romania LPI**

Source : *The Global Competitiveness Report 2012-2013, 2010-2011, 2007-2008*; World Bank, Logistics Performance Index, 2012, 2010, 2007

Consequently, we draw the conclusion that Romania is now better positioned in the logistics rankings. This represents in itself a confirmation of the thesis – supported throughout time by numerous Romanian researchers – of the commercial vocation of our country – geographical position, an open business culture, etc. –, respectively

of the competitive advantages in activities such as services, especially export-import ones.

### 3. Incoterms 2010 vs. 2000

The codified delivery terms – Incoterms – are a very useful tool for all the economic agents that are involved in international commercial transactions. They allow the users to define, with highest precision, the extent to which each of the parties is liable concerning one of the most important parts of the contracts: the delivery. As the literature shows, the proper use – which involves detailed knowledge – of the codified conditions is essential for the physical accomplishment of the foreign trade operations, as well as for the security of the economic agents, either of the exporter or of the importer. (Popa, 2006)

The high importance of the delivery conditions for the international contract, as well as the existence of various practices concerning the delivery, explain the concern for the codification of some rules in this domain, which would serve as a benchmark for the business sector. Starting with 1936, the International Trade Chamber in Paris published a set of rules with international applicability concerning the delivery of goods, named Incoterms 1936 (International Commercial Terms). These rules were revised in 1953, 1967, 1976, 1980, 1990, 2000, the last revision being in 2010 (publication 715)

If the previous modifications were continuous improvements to the code of practices – inside the same international paradigm – taking into account the practical experience of the merchants and the dynamics of the business environment, the last review means, in our opinion, not just a “technical” modification, but also a change in the paradigm: from international to global.

The two versions of the Incoterms present a series of common characteristics, as follows: the delivery conditions offer a precise definition of the obligations of the seller concerning the delivery of goods; of the transfer of the risks from the seller to the buyer, concerning the merchandise; of the division of the expenses between the two parties, during the transportation period; of the documents – or the equivalent electronic messages – owed by the seller to the buyer. *On one hand, even though* it does not regulate the transfer of the property right, Incoterms offers a clear solution for the problem of the transfer of the risks concerning the delivery of the merchandise at international level from the seller to the buyer. *On the other hand,* despite their *optional* character, the parties having the freedom to apply the embedded rules, Incoterms are used on a large scale in international trade. Even though they do not stand for an international law, Incoterms proved to be a highly useful tool in international trade. In the absence of an express reference to Incoterms 2000/Incoterms 2010, the parties may find themselves in front of some serious difficulties of interpretation of the contract in the process of its execution.

Incoterms 2000, like Incoterms 1990, are based on the classification of the rules in four groups – E, F, C, D – organized by the criterion of the increasing obligations of the seller. The rules are mentioned starting from the one which represents the minimum expenses amount for the seller – Ex Works (EXW) – and finishing with the one which implies that the seller would be charged the highest part of the expenses – Delivered Duty Paid (DDP).

Incoterms 2010 brings a series of modifications, among which we mention the followings: the reductions of the number of the delivery conditions: DEQ conditions were replaced by DAT (delivery at terminal), DAF, DES, while DDU conditions were

replaced by DAP (delivery at a denominated place), and the DAF condition was removed (See Table 1).

Another modification brought by the new version Incoterms 2010 consists of a new classification of the delivery conditions: the exclusive maritime delivery conditions (FAS, FOB, CFR, CIF) and the delivery conditions used in any other transportation mode (EXW, FCA, CPT, CIP, DAT, DAP, DDP).

**Table 1: Incoterms 2000 vs. Incoterms 2010**

Incoterms 2000				Incoterms 2010	
E	F	C	D	Omni-Modal	Marine Restrictide
EXW	FCA FAS FOB	CFR CIF CPT CIP	<del>DEQ</del> <del>DES</del> <del>DAF</del> <del>DDU</del> DDP	EXW FCA CPT CIP DAT DAP DDP	FAS FOB CFR CIF

#### 4. Competitiveness and the new Incoterms

A characteristic of the new Incoterms is the fact that – for the first time in the history of the elaboration of this code of commercial practices – the conditions are not exclusively applicable in international transactions, but in internal ones as well. Apparently it would concern the change from international to local (domestic); in fact, the new Incoterms regard a new structuring of the global economy in which the great economic areas have an increasing role. More specifically, Incoterms 2010 are applicable to some extended economic areas, either national (the USA) or regional (the EU), areas which are based on large markets with a unitary regulation (where borders are blurred). In fact these spaces have a dominant share in the global economy.

The statistical data below confirm this affirmation.

The external commercial changes of the EU are about 16% of the total exports and 17% of total imports; in the USA the percentages are 8,1% of total exports and 12,3 of total imports; however, in the case of the EU, the deliveries inside the community weight 62,4% of EU's total imports – the data is for 2011.

This reality implies major changes in the strategy of the firms which activate on the global market: their competitiveness is measured in global terms (not national), competitions is global, not international.

Another radical change concerns the two most known clauses from Incoterms, FOB and CIF. Therefore, we consider that their role is diminished by the inclusion in the category of the clauses that are used for maritime or fluvial transportation. Moreover, in some specific situations – such as transportation in containers – there were included important modifications in defining the clauses.

It is hard to foresee how this change will be perceived in that part of the business world which we call traditionalist (or conservatory, resistant to change). Until now, Incoterms 2010 are – to our knowledge – relatively poorly used as compared to Incoterms 2000. The extent to which they are applied represents a criterion of the evaluation of the way in which business is approached by the companies that

operate on the global market. The option for Incoterms 2010 seems to be the adoption of a global strategy concerning competitiveness. Another implication of the way in which FOB and CIF are defined in 2010 could arise in the domain of international statistics. Nowadays the exports are evaluated FOB and import are evaluated CIF (referring to the cost at frontier of the exporting country and cost, insurance and freight to the importing country). However, it seems that in the new vision the idea of a frontier itself is questioned or redefined in a certain way.

A third major modification brings into discussion the determinant factor of the globalization of the information nowadays, more precisely the electronic support and the internet: the new Incoterms recognizes and establishes the usage of electronic documents. With the formalization of the documents and electronic messages as being in conformity with the demands of the commercial circuit, the problem of the transfer from paper support to electronic support is brought into discussion, both in commercial correspondence and commercial formalities.

The electronic documents can be used if the parties convey so: therefore, the International Trade Chamber recognizes the importance and the reliability of the communication on electronic support in the global trade. The Internet represented one of the major forces of the globalization process; the globalization of business brings the Internet in front of a new challenge.

Last but not least, the new Incoterms bring opportunities to the companies to increase competitiveness through a proper logistic strategy; the extent to which these companies will succeed to integrate in the new trend – as soon as possible – will also be a measurement for their competitive capacity in the new context.

## **Conclusions**

International business will be characterized in the future, to an increasing extent, by a partitioned structure: the players on the global market, with the most chances to value the market potential; the firms with international activity (the classical foreign trade operations) and the companies with local dimensions. The most dynamic sector is previewed to be the one of the global firms.

In what concerns Romanian companies, the new trends mean new opportunities, given the fact that the category of global firms is no longer limited to transnational corporations – as it used to be – but also small and medium enterprises which operate exclusively or mainly on global markets are allowed. In this new plan there is room for the creation and the development of competitive advantages which are based mainly on the speed with which firms react to the change in progress, their adaptability to new conditions and their availability for intercultural communication. These last conditions are important characteristics of the Romanian business approach.

**Abstract.** *The educational system is one of the important factors in creating and developing the competitive forces of a country. The higher education provides the socio-economic environment with two basic services: teaching and research. The duality marks an entire history for higher education, but nowadays a new dilemma has emerged: economic efficiency (the university as an economic provider of services) versus academic competitiveness (the university as a research forum). In addition, a new challenge seems to be altering the future of higher education, these stemming from the massive increase in the demand for university teaching services: elite higher education, thus efficient, highly competitive academically (competitiveness), or mass higher education, adapted to the demand, with the primary role of harnessing knowledge through professional training (effectiveness).*

### **Education – a factor of competitiveness?**

Currently, competitiveness is defined in a relative manner, using comparative terms. Thus, an economy is more (or less) competitive than another country on the global market; a system (the educational one) is or is not competitive when compared with similar systems in other countries. This relates to the extent to which an organization / body has a higher performance than others depending on certain criteria.

But competitiveness - as a measure of performance - can also be defined in relation to a community's own project: realistically, i.e. in relation to the resources available and their degree of capitalization, respectively, idealistically, i.e. in relation to the expectations or dreams of that community. An economy/educational system is perceived as more competitive when it has a higher capacity to harness the national, material or spiritual "productive forces".

According to the OECD, competitiveness is "the capacity of companies, industries, regions, nations or supranational bodies, engaged in international competition, to ensure a sustained relatively high income by capitalizing on the factors of production, as well as a higher income by capitalizing on the labor force " (*Bulletin of the EU – Supplement nr.3/1994*, p. 17). The two dimensions are considered equally important, although debates on competitiveness tend to focus on the comparative approach.

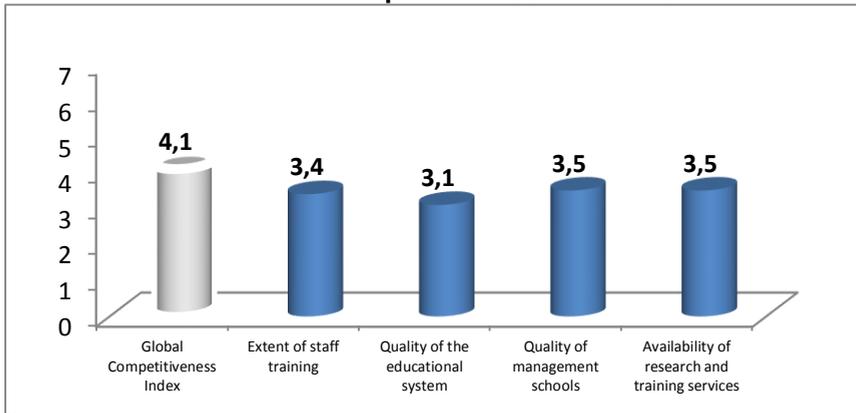

For a while now, The Global Competitiveness Report presents an annual ranking of countries in terms of competitiveness, based on the classification of its determinants

in several "pillars". One of these - the 5<sup>th</sup> Pillar - is *Higher education and training*, which, along with the 6<sup>th</sup> Pillar - *Goods market efficiency*, the 7<sup>th</sup> Pillar - *Labor market efficiency*, the 8<sup>th</sup> Pillar - *Financial Market Development*, the 9<sup>th</sup> Pillar - *Technological readiness* and the 10<sup>th</sup> Pillar - *Market size*, define the economies based on efficiency ( *efficiency-driven economies*).

The statistical data regarding competitiveness ranks Romania on a modest place at the global level and among the last places at the EU level. (See Chart 1)

**Chart 1**

**Romania: competitiveness indicators**

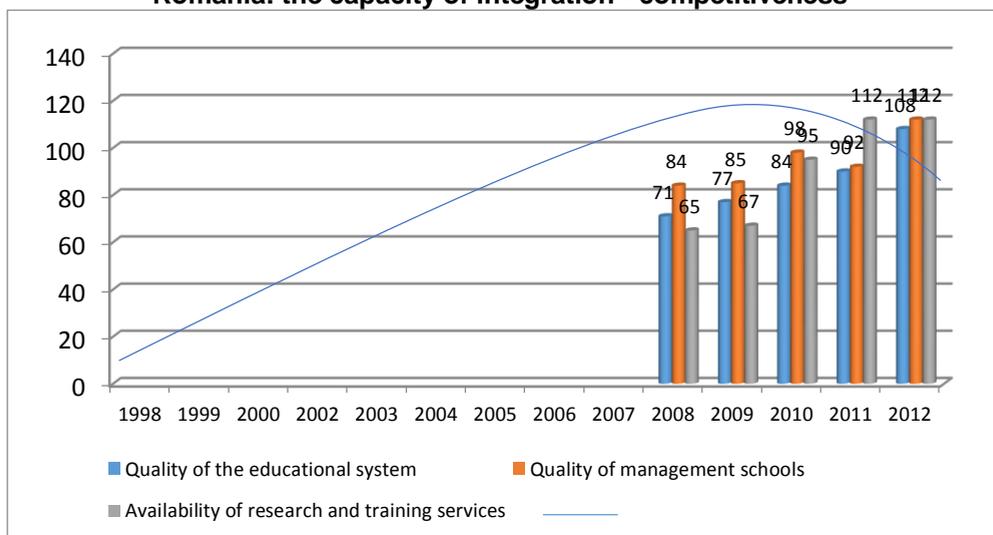

Sursa: *The Global Competitiveness Report 2012-2013*

Moreover, the data from the chart suggests that the educational system is perceived as less efficient (in terms of competitiveness) with respect to the national economy. In other words, the assessment of the business environment -The Voice of the Business Community - namely the opinion of those interviewed, i.e. persons with management positions in businesses, is more inclined towards the negative: the general index of competitiveness of Romania is slightly above the median, whereas the quality of the educational system is at the level of 3.1 (on a progressive scale from 1 to 7) and the management of schools at 3.5.

In a study conducted a few years ago, the conclusion reached was that "international statistics give us a disastrous image of the Romanian educational system, nearly 20 years after the Revolution. At all levels within the educational system – lower secondary, upper secondary and tertiary (higher education)– Romanian students' performances are less than mediocre " (Anton A)

**Chart 2**  
**Romania: the capacity of integration - competitiveness**

Source: *The Global Competitiveness Report 2012-2013, 2011-2012, 2010-2011, 2010-2009, 2008-2009, 2007-2008*; United Nations Educational, Scientific and Cultural Organization; [www.unesco.org](http://www.unesco.org)

On the other hand, the perception of the role of tertiary education in increasing competitiveness is increasingly negative. As presented in Chart 2, the share of those enrolled in higher education from the total population has more than tripled between 1998-2009 (after which a downward trend can be observed), and the competitiveness indicators in this area are getting worse (lower positions in the global hierarchy).

The increase in the number of those enrolled in the system of tertiary education is a general characteristic of former socialist countries. In Romania, the number of higher education organizations has increased from 46 in 1989 to 63 in 1993 and then to 126 in 2000: the number of students enrolled increased from 215.226 in the academic year 1991/1992 to 503.152 in 2000/2001 and continued to increase to 907.353 in 2007/2008 in all forms of education and study modes. Several factors explain this expansion: a) "the decompression effect" - the right to free enterprise earned after the revolution, on the one hand, and the massive demand for higher education services, on the other hand, have contributed to the expansion of the higher education system; b) "the synchronizing effect"- reconnected to the North Atlantic value system, the educational system has experienced an unprecedented diversification, transposed in the increased number of those integrated in the system (students, but also professors); c) "training effect"- which stemmed from the labor market in full expansion mode, in the context of an upward economic trend at the global and regional level. The crisis at the end of the last decade has stopped this expansion, primarily in its quantitative component.

### **Evaluating the educational system of Romania**

"In every country higher education is the moment of truth for the entire society" (Wikipedia, Romanian language edition, Education in Romania). The above

sentence summarizes a current perpetual outlook of the Romanian society: the educational system has more than an operating value (a factor of competitiveness), as it is also a factor in the creation and consolidation of institutions and national consciousness.

Therefore, we are interested in evaluating the higher education system from this perspective, by assessing the degree to which it meets the professional and civic training of the youth, those who will have in the immediate future business responsibilities and will represent "our distinct voice in the context of globalization". If we analyze, from this point of view, recent evaluations, we find that they are polarized in two directions: positive evaluations (from reasonable to very optimistic) and negative evaluations (from reasonable to catastrophic).

In a study conducted in May 2007 (Comsa M; Tufis C; Voicu B, 2007), 70% of the professors interviewed believed that Romanian higher education was as good as that in Western Europe, while only 59% of students agreed with this assessment. When asked "Is Romanian Higher Education at least as good as that in Western Europe?" the following results were obtained: 69% of professors, 58% of students and 50% of the adult population responded positively; when asked the question: "Are the professors of private higher education competent?" the following results were obtained: 58% of professors, 71% of students and 0% the total adult population responded positively.

On the other hand, in another official report (Miclea M, 2009) it is estimated that maintaining the current educational system in Romania is threatening the competitiveness and prosperity of the country. This educational system has four main problems: it is ineffective, irrelevant, unfair and of poor quality.

This latter view seems to be quite widely accepted among intellectuals. In a post found on a blog in 2011 (Diaconescu A, 2011), the author refers to: congenital illnesses (which pertain to the "heavy communist legacy"), chronic diseases (for example, the mismatch between theory and practice) as well as acute and endemic diseases specific to the last 20 years.

On the other hand in a comprehensive approach from the year 2010 (Vlasceanu L., Miroiu A, Paunescu M, Hancean M, 2010) it was considered that *"the overall picture of the qualitative state of our higher education, as it is reflected in the perceptions of universities, students and employers, is that of high quality"*.

A recent assessment of the educational system of Romania, which can be taken as a benchmark, is that of French Ambassador Philippe Gustin, whose initial profession was that of a professor. His Excellency states that Romania is not an underdeveloped country in terms of education. "You have an educational system that is highly efficient, particularly for creating elites; unfortunately this causes the loss of a million students." (school dropout appears to be the biggest problem in education).

Beyond these contrasting evaluations - sometimes taken to the extremes - the conclusion seems to be the same everywhere: the Romanian educational system needs to be reformed.

### **What does "modern university" mean?**

Since ancient times, there are two views on school mission: one that aims to foster the development of human personality, and one that aims at preparing citizens to participate in public affairs. For Plato, the purpose of education is to cultivate the intellect to form personalities able to understand the universal laws, the essence of

life processes and phenomena; in contrast, to Isocrates the purpose of education is the formation of a personality able to participate in solving the problems of society. In other words, an education centered on the man as a cultivated person, on the one hand, and as a member of the society, on the other hand.

However, the development of higher education has not been made through strong options for either of the two orientations - "culture" or "civilization" - but through the specific positioning in the space defined by the two coordinates. University means education, cultivation of the values, formation of human personality. But the university also means education, knowledge transfer and creation of intellectual skills.

Regarding school today, several dimensions should be highlighted.

A first approach is due educator and American researchers Abraham Flexner, sustaining that "modern university is characterized by suitability for specific requirements of each stage of social economic development. University is "an expression of time or" influencing the present and the future of the society.

Another dimension of "modern university" is revealed by the philosopher Jacques Derrida: academic freedom, unconditional freedom to ask questions and make suggestions "search for truth, without any condition, is what defines this condition.

A third feature is revealed by what one author (Ramaley J, 2004) calls the "engaged university" or the society involved in solving the specific problems of that time. The rigor of the research, the quality of the educational product and the organic link with the community to which it belongs and the impact on the quality of life of citizens nationwide and globally are the key success factors of the university of the XXI<sup>st</sup> century.

Finally, another approach (The Boyer Model of Scholarship) assumes that more than ever in history, the university must be involved in the social, economic and ecological environment to which it belongs. It should not only help to increase the dowry of knowledge and intellectual values of the society, but also to solve the specific needs, individual and social, belonging to the environment in which they develop.

### **The reform of the Romanian higher education system**

The history of education in Romania (see Wikipedia) highlights two crucial issues for our education. The first problem is the delay we have in creating high education (Univ. Iasi, 1860, Univ. Bucharest, 1864, Univ. Cluj 1919); in a recent paper (which has given rise to controversy) Paprika Lucian history emphasizes that delaying in the creation and development of institutions is due to persistent cultural and economic gaps between Romania and the western world. (Boia L, 2012) A second problem is the existence of turning points - reforms that marked the development of higher school to us. Spuru Haret Reform 1880;The inter war Reform, basically a consolidation and expansion of the previous reform; drastic changes in the communist experiment (48-49 copying Soviet system; partial liberalization in 1958; 1972 nationalist Stalinist system).

Beyond the performance deficit during that period, caused in large part by the tendency towards islanding (nationalism) and ideology (communism) of the system and consequently of education in general, of the university in particular, one embodiment of the system is generally recognized (and not infrequently evoked by the nostalgic): efficacy, its coverage (literacy etc.) respectively the success with respect to mass education.

After 1990, there were two important events marked by the enactment of a special law: Law Education 1995 Education Law nr.1/2011.

After 1990, the question of the reform was put in terms of the need to raise the quality of education in the context of general restructuring in the post-communist times. The first stage of the reform in education scare was marked by GEO. 75/2005, then enacted by Law no. 87/2006. There were two conceptions of quality at the moment: one in which quality is related to their institutional goals (fitness for purpose), and another where the quality is related to a set of predetermined and universal standards (standardization). Although [8] mentioned in the preamble of the law above mentioned, implicitly, both orientations, the main legislative subsequent provisions frame the Romanian system of quality assurance in the second philosophy.

Translated into terms we use above these guidelines would mean that, the first case it is about effectiveness, and the second about competitiveness. This option can be related to a famous dispute of the interwar period – the one of the followers of "synchronism" and respectively of the protochronism (with its postwar extension); with reference to a problem highlighted from the first period of the synchronization of Romanian culture with western culture – the risk of "forms without substance". A second stage of reform was established by the Law from 2011. This time it is about a determined approach in terms of "competitiveness" in the sense of imposing a model that meets the criteria set out for the universities of the North Atlantic area. This reform has several features. First, a classification of universities into three categories: universities focused on education, universities for education and research, universities for advanced education and research. We are talking therefore about the establishment of a hierarchy – matching the American model – of the higher education institutions, with consequences on the types of study programs that these universities can provide (bachelor, master, doctorate), as well as on the level of funding from the budget. Should follow the "hierarchy of study programs in which there would be involved, as well as in the first stage of classification, independent foreign experts".

Then, a more dynamic approach of ' the change in generations' in higher education, through forced retirement of teachers – elders – who met the criteria (age of retirement, determined by Western model - French) and promotion of the superior teaching positions - youth - which meet the criteria (for promotion ,established by the ministry after the Western model). Finally, imposing as an absolute criterion of professional assessment of the scientific research reflected in articles (ISI) : the article ("creation science") is more important than the book ("mere compilation"). Finally, the university must become 'student centered', 'students are considered "partners" of institutions of higher education and equal members of the academic community. "Basically, "The law provides penalties for universities to their curricula admit more students than capacity approved school", a *numerus clausus* established after the approval of that capacity of schooling.

There is no chance of a temporal perspective, essential to assess the effectiveness of reforms since the project was seriously adjusted by subsequent legislation. We can say, however, that the project was a bitter effort of making more competitive – in the vision of the promoters – the higher education. In fact, in the post-1990 we witnessed the confrontation of two types of reform; one that, starting from the model inherited, is trying to adapt to new conditions – with significant compatibility

adjustments with the European model – and a new American model, imposed by law.

The effectiveness of legislation proved to be relatively low, the educational system in general and the university in particular, facing many changes through decisions that changed or altered the spirit or even the letter of these laws. The perception of education reform is generally negative, while the assessments regarding the capacity of the education system are generally optimistic – a paradox of the current state of education.

## Conclusions

First, a university is not competitive by law (Decree, emergency ordinance, etc.). Through legislation, with lasting effect, the effectiveness of the educational system may be enhanced, as well as its ability to integrate, educate and train young people as intellectual figures (Plato) and active citizens (Isocrates). The competitiveness of the schools depends on the extent to which they enable assertion of the elite system – students and teachers – capable of generating new values within that system and to determine the effects of training on the entire university environment. The affirmation of the elites is an organic process that takes place with the development of the educational system; pre-requisite separation on categories (by circumstantial criteria) can be deeply counterproductive.

Secondly, the Romanian reference model must remain the European type, even if adapted to the dominant trend – the Anglo-Saxon –specific to the globalization process. If the education reform in 1880 aimed at modernizing the Romanian education system in accordance with the requirements of design and development of the national state (the national consciousness, national values), in the XXI<sup>st</sup> century the reform in Romania should aim at the performance of the education in relation with the requirements of the European and global economy.

Third, a modern university means a university corresponding to its time, one which has a history and a future perspective. In other words- and despite what the phrase suggests prima facie – it is fundamentally the university of today, not of tomorrow. The university of tomorrow is just a project for the evolution of the university of today.

## THE HUNGARIAN CRISIS: AN AUSTRIAN SCHOOL EXPLANATION

**Tóth András**

*Institute of Political Sciences, MTA TK, Budapest, Hungary  
tothandhu@gmail.com*

**Abstract:** *The Hungarian model was heralded as one of the most successful post-socialist way of integration into the globalised world economy and European economic area in the nineties. Currently, Hungary is suffering from a full-blown crisis 1996 onwards. Increasingly large number of Hungarians is losing their faith in political parties, institutions, democracy and in market economy. The government, elected in 2010 by supermajority and still enjoying a broad support despite the deepening recession, condemns the development path taken after 1989 and openly rejects the wrong model of the last 20 years. The government intends to build a new economic model following a model, which one can call a model of economic nationalism as the only way out of the crisis. The paper intends to portray, through the case of Hungary, how economy and politics is interconnected, and why political elites are choosing a credit fuelled development path. The paper intends to portray how a credit fuelled growth was induced by politics and ended up in tears. Moreover, the paper describes the consequences of pro-etatist shift in the public sentiment due to the alleged “market-failure”, which was in reality a crisis, at first place, created for political purposes by political means. This article, based on the Austrian business cycle theory, argues that the tragedy of Hungary was that it went through a government inspired spending binge in the first half of the 2000s. The deficit spending of the government was accompanied by the expansion of credit by the commercial banks, mostly denominated in Swiss francs. The combined effect of deficit spending and credit expansion was the build-up of debt and loss of cost competitiveness. The 2008 crisis ended the credit fuelled development path and has started the long and painful period of deleveraging crisis. On the other hand, the Hungarian crisis is a post-Keynesian crisis. **JEL Classification:** *A14*

The Hungarian model was heralded as one of the most successful post-socialist way of integration into the globalised world economy and European economic area in the nineties. Currently, Hungary is suffering from a full-blown crisis 1996 onwards. Increasingly large number of Hungarians is losing their faith in political parties, institutions, democracy and in market economy. The government, elected in 2010 by supermajority and still enjoying a broad support despite the deepening recession, condemns the development path taken after 1989 and openly rejects the wrong model of the last 20 years. The government intends to build a new economic model

following a model, which one can call a model of economic nationalism as the only way out of the crisis.

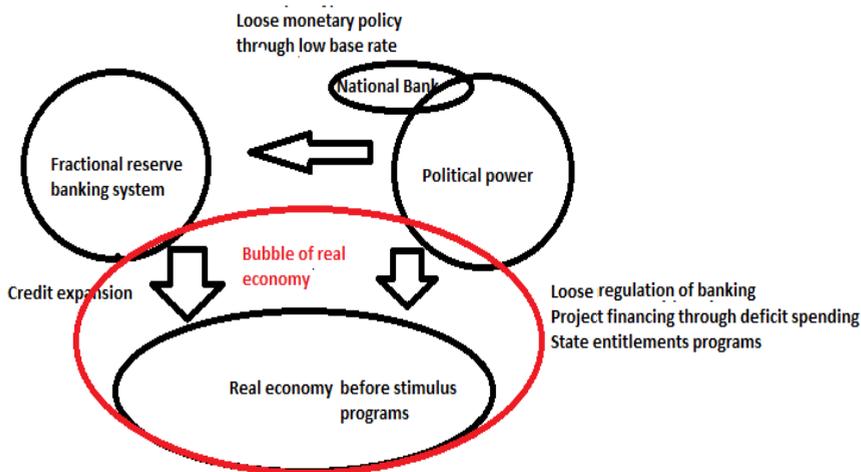

The paper intends to portray, through the case of Hungary, how economy and politics is interconnected, and why political elites are choosing a credit fuelled development path. The paper intends to portray how a credit fuelled growth was induced by politics and ended up in tears. Moreover, the paper describes the consequences of pro-tatist shift in the public sentiment due to the alleged “market-failure”, which was in reality a crisis, at first place, created for political purposes by political means.

This article, based on the Austrian business cycle theory, argues that the tragedy of Hungary was that it went through a government inspired spending binge in the first half of the 2000s. The deficit spending of the government was accompanied by the expansion of credit by the commercial banks, mostly denominated in Swiss francs. The combined effect of deficit spending and credit expansion was the build-up of debt and loss of cost competitiveness. The 2006 Hungarian budget crisis halted the deficit spending, but induced further credit expansion through the banking system. The 2008 worldwide crisis ended the credit fuelled development path and it has started the long and painful period of deleveraging crisis in Hungary. On the other hand, the Hungarian crisis is a post-Keynesian crisis. It had broken out when the state was already heavily indebted and the managerial state fully developed within the constraints of the capabilities of the Hungarian economy. Thus the government had not opportunity to overcome the crisis through deficit spending, following the Keynesian script. The paper argues that Hungary has chosen the wrong path by opting for economic nationalism and blaming “markets” for the crisis. Following the tenets of Austrian economics theory, the paper argues that statist economic nationalism would only deepen the crisis through creation of regime uncertainty and as a consequence of ever increasingly curtailing of freedom of private business through selective regulation, cartelisation and through punitive taxation.

### **The Austrian business cycle theory**

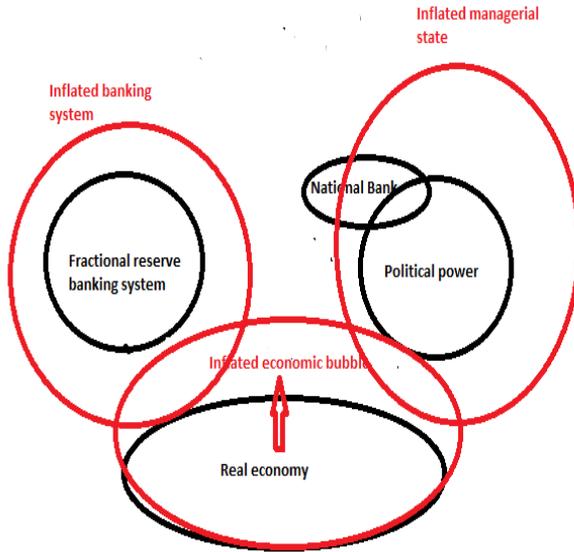

The heart of the austrian business cycle theory, first developed by Mises (1921) is the phenomena of not savings based credit expansion engineered by the state through deficit spending and the fractional reserve banking system, enabled by the loose monetary policy of central bank. The boom is followed by bust, a credit-crunch. Market processes are inevitably ending the boom sooner or later and causing a painful deleveraging process, undoing of malinvestments generated by the artificially generated and unfounded credit boom. This deleveraging process causes a wider political crisis. The cycle of unfounded and unsustainable boom and consequent crisis and deleveraging process is the heart of the Austrian business cycle theory (see more: Ebeling, 1978). According to this theory, the credit boom instigated by the fractional reserve banking system, without previous savings, creates an artificial boom. None the less, the arrival of the managerial state and the base rate policy of national banks creates previously unseen power to induce an expansion of economic booms through deficit spending by the state and the credit expansion by the banking system (see: Figure 1.).

Figure 1:

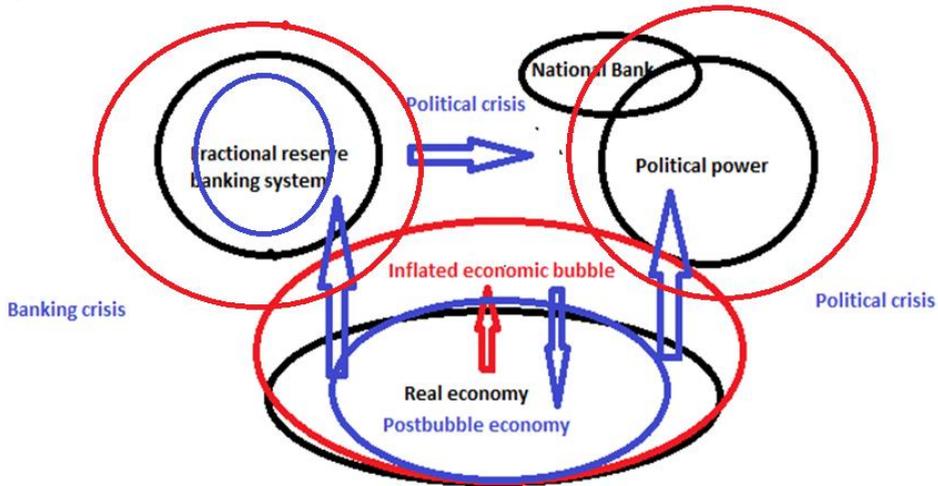

The credit and cheap financing boom distorts the calculations of the entrepreneurs, consumers and the state. Entrepreneurs, due to cheap credit and abundant orders, are overestimating the future trend of volume of capital offered to invest and that of consumption. Consumers are developing falsely optimistic scenario of real wage growth and entering into a spending binge. The boom, leads to malinvestments (Mises, 1949), a cluster of entrepreneurial errors (Rothbard 1962). The state, which initiated the boom through deficit spending and credit expansion, in turn is experiencing a revenue growth. The revenue growth induces further expansion of public investment and entitlement programs, the rise and extension of managerial state (Gottfried 2001). As a consequence, there is a parallel and mutually reinforcing inflationary growth of the real economy - consisted of enterprises and consumers – the fractional reserve banking system and the managerial state is taking place at the expense of debt accumulation and building up of credit pyramids. A kind of Ponzi-scheme style expansion is taking place across the economy, in which growth is based on ever growing credit expansion schemes. The seemingly never ending growth is going ahead causing an ever increasing rise of consumption, until there is not emerging an external obstacle, which would turn the tide. Overconsumption in a finite word inevitably leads to price inflation and/or rises of asset prices. Price increases and/or interest rate rise by the central banks as response to price increases are bursting the bubble (see: Figure 2.).

Figure 2:

Economic actors are facing with the moment of truth: they have mistakenly incurred debt to finance long term projects, which are now turned to be unsustainable due to asymmetric price changes. Entrepreneurs, in turn, are realising that earlier investments are not sustainable, do not produce the expected revenue stream and consumers are unable to meet with credit instalment payments. They immediately draw the conclusion: they should cut back consumption, terminating the half-ready investment projects and cut costs and expenses. The crisis of the real economy begins, which quickly had its impact on the banking system. Credit translates into unsustainable debt. Faltering instalment payments are provoking shortage of bank capital, runs on banks, and may lead to full-swing banking crisis. The collapse of credit further increases the crises of the real economy. Banking crisis feeds the deeper and deeper crisis of the real economy. This leads further to wage cuts, unemployment, the collapse of livelihood and stability of wide sections of the society. Through instability of livelihood, the crisis of the real economy translates into political crisis. The black swan (Taleb 2010) event is becoming reality: the artificial boom based on unfounded credit expansion turns into overall crisis present in the real economy, banking system and in the political system. (see: Figure 3.).

Figure 3:

The Hungarian crisis is a post-Keynesian crisis. It broke out when the state was already heavily indebted and the managerial state had fully developed within the constraints of the capabilities of the Hungarian economy.

### The characteristics of the post-socialist Hungarian model

In the early nineties had formed the three most important feature of the post-socialist Hungarian economy: 1) highly efficient export oriented FDI sector with low level of interconnected local supplier base 2) non-efficient and partly tax-evasion based domestic SME sector serving local markets and in fierce competition with foreign products and service providers, 3) a relatively large welfare state and state bureaucracy.

### Tensions of the Hungarian model

There were three major sources of tensions of the emerging model. First, it have emerged the widespread feeling of fear from insecurity, the sensation of exploitation and anger with the increasing inequality after many decades of relative equality. Secondly, the takeover of flagship firms by multinationals, the low effective tax level on FDI operations. It created a feeling of negative discrimination of domestic entrepreneurs and the sensation of being exploited by foreign companies, by large multinational companies. Thirdly, the benefits of recovery have spread unevenly within the country. Large areas of the country remained depressed, especially, far away from the Western border of Hungary, from highways and rural areas far away from revitalised industrial centres.

The segmented success of Hungary in building a post-socialist economy is increasingly translated into political tensions. There had been formed two major blocks of political parties following the democratic transition. One block was formed by the alliance of left wing MSZP (Hungarian Socialist Party) together with the progressive liberals. The other block was formed around the right wing FIDESZ (Alliance of Young Democrats). MSZP adopted a pro-European third way policy, influenced by Tony Blair, and argued for extensive welfare state combined with open

market economic order. FIDESZ increasingly adopted economic nationalism, claiming that the state should support domestic entrepreneurs and reinforce state participation in the public service sector.

### **The derail of the original model and turn to state led development model based on deficit financing and debt build up**

Around 2000, was the turning point. The FIDESZ led government, elected in 1998, followed a prudent economic policy. None the less, this policy was heavily criticised by MSZP, which demanded “welfare transition”. Facing with loss of popularity, the FIDESZ turned to Keynesian-style state financed economic development policy too boost consumption. In the heated 2002 elections campaign, MSZP outbid the governing FIDESZ by promising wide scale welfare measures. The MSZP has implemented all the headline pledges made in the elections campaign and continued the Keynesian policy of deficit spending.

Joining the EU, in 2004, meant that Hungary should have observed the conditions set by the European Stability Pact (ESP). The government had to introduce various packages to reduce budget deficit 2003 onwards. This policy change, however, led to rapid loss of popularity of the government. In autumn 2004, facing with the possibility of losing elections in 2006, MSZP has opted to change and returned to debt build up to finance the rapid increase of the internal consumption. Commercial banks, to circumvent the restrictive monetary policy of the national bank, had expanded credit employing a scheme based on Swiss franc. The government had not intervened, despite having receiving warnings about the potential negative consequences of building up debt in foreign currency.

### **Crisis and the collapse of the post-socialist development model**

MSZP easily won the 2006 elections. Winning the elections, however, the re-elected government had to meet with the EU demand to introduce severe cuts in budget spending. The sudden U-turn of the government was a bolt from the blue. Things were made worse by leaking out a speech of the Prime Minister in autumn 2006, in which he admitted in a closed meeting, that the government lied during the elections campaign and mislead the electorate to gain re-election. The speech provoked a deep political crisis. The outbreak of the 2008 crisis made things worse. The fall of the Hungarian economy was especially deep as the state continued to cut costs.

In this period, the FIDESZ followed a staunch opposition policy. Opposed any reform, and demanded Keynesian style measures to redress the crisis. FIDESZ promised a strong state, which would support Hungarian entrepreneurs and middle classes instead of unbridled neoliberal policies.

### **The “revolution” of economic nationalism**

The 2010 elections were won by FIDESZ with two-third majority. The supermajority allowed to the government to break free from any constitutional limit and the government put forward a goal of re-organising Hungary. FIDESZ used the supermajority to implement economic nationalism (see Mises 1944) and to assist the strengthening of a loyal entrepreneurial class through covert and explicit cartelisation of certain sectors of the economy. The stated goal of the government is to create a new and more indigenous growth model based on strong government after the alleged the failure of the globalised and FDI dominated post-transition societal model, which only served to exploit the Hungarian nation by foreign companies and

speculators, especially in public services, banking and retail trade sector. This strategy required selective legislation at the expense of neutral concept of rule of law.

There were, however two constraints on the government. In one hand, given the lack of competitive domestic industrial base, the government is forced to support the presence of manufacturing FDI and limit economic nationalism to service sectors. Secondly, EU insisted to maintain budget deficit at 3% for 2011 and at 2.5% for 2012, and thus effectively blocked the initial plans of FIDESZ to finance through deficit spending the re-engineering plans. To circumvent financial limits set by the Commission, the government acquired the accumulated wealth of private pension funds. The ending the private pillar of pension system also had the beneficial effect that it had lessened the annual deficit of the budget by 1-1.5% of the GDP, easing the meeting with the strict conditions set by the Commission. Additionally, the government levied special taxes on a number service sectors, mostly dominated by large multinational firms, to increase her revenue. It is rumoured widely in the financial press that the special taxes are also serving to implicit putting pressure on these companies to leave Hungary and hand over their markets to domestic companies.

The results of three years of re-engineering are mixed. Politically, economic nationalism is a winning ticket. The government has retained a relatively huge support despite the recession. Economic nationalism proved to be a successful strategy when large segments of the population lost their hope in the globalised market economy, and put the blame on foreign speculators and banks for the crisis. A large section of the population hopes to come out from the crisis by ending the exploitation by foreign companies.

None the less, the economic results are increasingly contradicting to these hopes. The Hungarian economy 2011 onwards fell into recession. Investment has fallen to a very low level. It is widely argued that regime uncertainty (Higgs 1997) is the major reason for the low investment level caused by cartelisation in certain sectors, legal uncertainty created by ever changing and selective regulation, fear of seizure of wealth through punitive taxation. Hungary is increasingly becoming an outlier in the region, caused by inward looking policies and ever deepening recession. Economic nationalism is increasingly at odds with the European regulation ensuring the operation of the European single market.

### **Discussion: Austrian economic cycle theory and its interrelationship with politics**

The paper through the example of Hungary showed how develops an unsustainable, credit fuelled economic model mediated through party competition for power in a democratic system. Winning in the next elections is an unquestioned priority for political parties. For governing parties one of the major arguments for re-elections is economic growth. Thus governments do their best to engineer growth with "good" government policies and redistribute the dividends of growth for those layers of the society, which deemed to be important for the re-election for the governing parties. It was the reckless attitude of the major political parties to secure political power for themselves is the major culprit for the excessive debt build up for the state and for allowing the banking system to offer forex based credit for consumers and companies. Six years of party resulted in a long agonising recessionary period. During the long recession, the MSZP led government was unable to unleash

Keynesian anti-cyclical deficit spending due to the high government debt level and had to implement austerity measures, which deepened the recession.

The impact of debt crisis and the long crisis, however, had undermined popular trust in markets, which was anyway low given the low trust nature of the Hungarian economy (Bartha 2012). The FIDESZ ably exploited the wishes of the population for a quick fix and made to believe that a strong government could overcome the crisis and ensure security. Winning the 2010 elections, FIDESZ implemented the policy of economic nationalism, and pursued a blame game against banks and foreign investors. Blame game and feeding the hope for development through profit-repatriation from foreign actors is provided an opportunity for the government to legitimise crumbling down of rule of law to be able to legislate special punitive taxes and renationalisation in selected public service sectors. Punitive taxes afforded new sources of revenue for the government. Another source of additional government revenue came from acquiring the private pension funds by the government through punitive legislation. With these measures, the government was able to upkeep the active managerial state providing justice and offering paternalistic protection. Unfortunately, for the long term prospect of Hungary, economic nationalism and the crumbling down of rule of law, which is a necessary consequence of omnipotent government, regime uncertainty is undermining business confidence and reducing long term growth potential of the country. Increasing isolation, ever deepening recession is the price for economic nationalism. None the less, a selectively punitive high tax regime, the ever increasing fear of arbitrary state intervention may just works against the hopes of average Hungarians, that state could reignite growth.

**Abstract:** IMF has been created to make international cooperation on financial matters stronger and for solving the problems of balance of payment. However, the IMF formed policies in order to solve problems of balance of payment till the 1980s, expanded its effectiveness much more by controlling the structural adjustment programs after the 1980s, and undertook the role as an international lender of last resort on crises caused by globalization trends. In developing nations, foreign and domestic deficit occurred due to infrastructural causes that have created economic instabilities portrayed through inflation and unemployment. Especially foreign debt problems sourced by the foreign trade deficit transformed into an economic crisis for these countries. Many countries affected by such economic crisis applied to IMF and its Stabilization Program with the aim of providing economic stability in the hopes of recovering. The important thing here to point out is that the economic programs used by countries during their economic crisis are supported by the IMF in reality. In this situation Mexico and Argentina can be given as a good example. IMF has undertaken the same mission in Turkey with seven stabilization programs put in practice and nineteen Stand-By Arrangements between them. But IMF has failed many times in Turkey just like in many developing countries. This is because IMF did not take into consideration economic and social structure of countries in stabilization programs put in practice. Today, Turkey has reached to an important point from the way of its relationship with IMF; more clearly, Turkey is determined to achieve its future without IMF. Turkey-IMF relationship in the framework of stand-by agreements in the past half century of our economic and political history has come to an ending point. After a period of 51 years of intense relations, Turkey decided to determine its calculations of credit limit by the way of advantages and disadvantages and continue its relations in this way. In this context, this study will try to prove therotically that Turkey will put in place to foreign credit support with the purposes of carrying out stabilized policies and protecting itself from financial shocks. Finally, Turkey will contact IMF with requirements of the rules and regulations that are in its advantage.

**Keywords:** IMF; Stabilization Program; Stand-By Arrangements; Turkey.

**Jel Classification:** E02, F55.

## **1. Introduction**

Realizing economic development and its continuity is difficult, but is a requirement for a country. The basic problem faced by many countries who are trying to establish economic development is domestic and foreign instability. Economic stability is defined by the balance of both domestic stability; such as full employment, equilibrium level of income and price stability and also by foreign stability; such as balance of payments stability. In a country that hasn't realized economic stability, negativness in each and also economic crisis can be seen as sosyo-economic problem such as inflation, deflation, stagflation, poverty, inbalance of income distribution. For that reason, the most important task is to provide economic stability and to insure sustainability by economically developed and developing countries.

Developing countries generally need foreign support to overcome economic crisis sourced by domestic and foreign imbalance. One of the international organizations that support countries like these are International Money Fund (IMF) and World Bank (WB). IMF takes a role by strengthening balance sheet, providing price stability and macro-economic performance, applying financial sector policy and granting credit for needer countries. WB is generally interested in long-term development and policies in reducing poverty.

Countries that want to provide economic stabilization have applied monetary and fiscal policy for domestic economic stabilization and foreign trade policy for liberization in foreign trade with the guideness of IMF-supported Stabilization Program

In this study, the last IMF-supported Stabilization Program in Turkey will be examined after mentioning the role and importance of IMF in the world and then will determine the last perspectives of Turkey-IMF relationship.

## **2. IMF Stabilization Programs and the Role of IMF in World Economy**

### **2.1. IMF Stabilization Programs**

In developing countries, foreign and domestic deficits are caused by structural reasons, manifesting itself in the form of inflation and unemployment, leading to sustained economic instability. Foreign trade deficits of these countries, especially with the heavy foreign debt problems, transforming the conditions of instability and crisis stabilization policies are implemented (Çelebi, 1998). GDP, employment and large balance of payments fluctuations in the level of prices in order to minimize the stabilization policies is considered by countries as a solution to economic imbalances. These elements according to their facilities can be divided into five groups, financial, monetary, external, control and enterprise.

In order to achieve the desired purpose of the application of stabilization policy, the country's political, economic and social elements being taken into account all or some of the above-mentioned instruments must be used according to the different priorities and measures. Brought into line with the country's stabilization policy instruments based on the structural characteristics of an effective, efficient and appropriate solutions will be higher than the probability of making an undeniable fact. Aims to correct imbalances in the financial and the real sector of the economy, stabilization programs in developing countries are often implemented for many years. The main causes of countries implementing radical stabilization programs are accelerating inflation, balance of payment bottlenecks; the serious imbalances in the financial markets and the real sector (Bahçeci, 1997). In other words, the main

purpose of the economy of goods, capital and foreign exchange markets is to provide equilibrium prices. Stabilization programs, which are the application of stabilization policies in a country, are used to combat the current economic instability.

Stability and/or structural alignment programs are called in general a lasting improvement in the balance of payments and foreign inflation decreasing in velocity, or both, as the composition prepared in order to achieve the overall macro-economic targets as economic measures defined in the package. External financial support to developing countries to implement IMF-type stabilization policies (programs) are based on Monetarist thinking, orthodox stabilization programs (Bayraktutan & Özkaya, 2002; Boockman & Dreher, 2003). IMF-type stabilization programs can be based on three key elements. The first is a short-term policy implementation to address balance of payments disequilibrium; secondly, the effectiveness and providing growth to the mechanism of the free market, and the creation of the necessary arrangements for it; thirdly, it's able to ensure that countries that get financial support from the IMF guarantee their ability to pay its foreign debts (Zaki, 2001). In addition to these qualities the IMF, the WB and the U.S. Treasury created the "Washington Consensus," and after obtained measures in accordance with the basic ideas of IMF-type stabilization program created a package of measures that have been applied in all countries particularly in Turkey.

Today, the IMF's proposed stabilization programs is expected to bring under control the problems of inflation and the foreign deficit in the short term due to tight fiscal and monetary policy and devaluation. In medium and long-term supply-side policy instruments, an increase in the production and use of resources more efficiently, and making infrastructure investments, property and the opening up of the economy through liberalization of capital movements and a broad privatization will be provided by going along with the growth of free market economy by strengthening the economic instability has been suggested to permanently resolve economic instability (Çelebi, 1998; Joyce, 2012).

## **2.2. The Role and Importance of IMF in World Economy**

After 1980, many developing countries have made free capital accounts. Thus, financial liberalization is experienced all over the world, and the ability and speed of movement of international capital be increased. In the 1990s, advances in the field of communications, access to information, along with facilitating the phenomenon of globalization has increased the interdependence of the world's financial markets. Addition to financial integration, this kind of communication and the emergence of new financial instruments and transactions, and has widespread the international credit system. The process of international expansion of the credit system as well as an increase of speculative capital movements have occurred balloons that could cause booms in financial markets. Since the early 1990s as a result of all these developments, speculative capital movements directed by countries, in spite of their shortcomings of infrastructure have made quick financial liberalization are developing countries and have suffered severe crises in the fields of finance and banking. Balance of payments crises arising from the same period has been intertwined with the financial crisis. In order to get rid of the economic crisis, many countries turned to the IMF and to its stabilization programs to ensure economic stability. An important point to note, that many economic crises is that the programs implemented at the beginning of the crisis are IMF-supported programs. However, Mexico and Argentina are good examples. According to a study by Hutchison and

Noy covering the years 1952-1999 country groups that implemented IMF-supported stabilization programs are shown in Table 1 below.

**Table 1: Approved Programs (1952-1999)**

	<b>Short-Run SBA</b>	<b>Long-Run SBA</b>	<b>SBA Per Country</b>
<b>Latin America</b>	284	11	11,7
<b>Asia</b>	101	13	6,8
<b>Middle-East</b>	33	00	5,3
<b>Africa</b>	229	72	7,2
<b>Others</b>	113	04	3,2
<b>Total</b>	<b>760</b>	<b>100</b>	<b>6,8</b>

Source: Hutchison, M.M. & Noy, I. (2003) "Macroeconomic effects of IMF-sponsored programs in Latin America: output costs, program recidivism and the vicious cycle of failed stabilizations. *Journal of International Money and Finance*", (22), p.p. 991,1014.

Table 1 above shows the approved and implemented stabilization programs by IMF most are in Latin American countries (11.7 per country program), while the Asian Region countries were ranked third (6.8 per country program).

**Table 2: Stand-By Arrangements (2000-2011)**

<b>Years</b>	<b>SBA</b>	<b>Years</b>	<b>SBA</b>
1999	5	2006	5
2000	11	2007	3
2001	11	2008	8
2002	9	2009	13
2003	10	2010	5
2004	5	2011	14
2005	6	2012	5*

Source: IMF. (2013) "Annual Report / 2011 and 2012", [Online], Available: <http://www.imf.org/external/pubs/ft/ar/index.htm> [22.03.2013]. \* Until April-2012.

However, stand-by arrangements with IMF have decreased seriously in the world since the 2000s, as seen from Table 2. Member countries realized only about 110 stand-by arrangements from 1999 to the end of 2011 (with the estimated numbers of April, 2012). Especially, in 2007, there were only 3 stand-by arrangements between IMF and member countries in the entire world. But, the number of stand-by arrangements began to increase with the 2008 global economic crisis and after that reached to 14 arrangements in 2009.

### **3. Turkey – IMF Relationship**

#### **3.1. IMF History for Turkey**

Turkey has been a member of IMF since 1947. This membership for Turkey was the first step of an open economy with the aim of preventing foreign deficit and increasing direct foreign investment (Boratav, 2003). So Turkey's economic and political

relationship with other countries began by joining international organization after 1946. In this context, Turkey that wished to have closer economic and political relationship with Western Countries realized it with its membership to IMF and World Bank with the law number 5016 on the 19<sup>th</sup> of February 1947 (Karluk, 2002).

**Table 3: Stand-By Arrangements of Turkey**

SBA - Date	Duration (Month)	Canceling Date	Amount (million SDR)	Letter of Intend (Signing Date)

Source: Mahfi Eğilmez, "IMF ve Türkiye", *Radikal Gazetesi (Newspaper)*, 19<sup>th</sup> of May, 2005.

It will be appropriate to tackle Turkey – IMF relationship in two different time periods as official participation and actual participation. Turkey has a 66 year history with IMF according to the date of membership; but actually has a relationship of 61 years with the signature of the first Stand-By Agreement on the 4<sup>th</sup> of August in 1958.

According to IMF Principal Agreement, member countries are represented by treasury secretary (IMF articles et al. 1993). Fiscal agent in Turkish Undersecretariat of Treasury represent Turkey in IMF. By the way, Turkish Lira Accounts belongs to IMF and has kept in the Central Bank of Turkish Republic as a responsible entity of money in Turkey. Also the Secretariat of Treasury represents Turkey as a "Governor" and the President of Central Bank represents Turkey as a "Vice-Governor" in the board of governors of the bank in the IMF.

Turkey gained 8<sup>th</sup> article status (status for countries which liberate capital movements) by promulgating the protection of the value of Turkish Currency Law in 1989. Status changing of Turkey was declared to the entire world by IMF on the 3<sup>rd</sup> of April in 1990 (Eğilmez & Kumcu, 2001).

As a result of 11th Quota Increasing Discussion completed in 1998, quota of Turkey was increased to 964 million SDR. The sum of fixed and variable votes of this quota is 9.890 (0.45% of all votes) in terms of voting power at IMF Executive Board in March, 2004.

Turkey implemented 19 Stand-By Arrangements with IMF after 1958 with the aim of having economic stabilization again. Turkey used some opportunities of IMF such as “Stand-By Arrangements,” “Consolidated Fund Facility” and “Additional Reserve Facility” within the framework of these arrangements. There were 7 comprehensive stabilization programs among these 19 Stand-By Arrangements in the past 55 years. All these arrangements with IMF are shown in Table 3 and as it can be seen from this table, Turkey has a close relationship with IMF in those years. So, the last program with IMF called the “Program for Transition to A Strong Economy (PTSE)” must be examined for evaluating the past and the future of Turkey-IMF relationship.

### **3.2. The Program for Transition to a Strong Economy**

The main purpose of PTSE formed by two-stages on 14th of April and on 15th of May in 2001 was to remove the confidence crisis caused by exchange rate regime and to create an infrastructure for restructuring of the economy and public administration. Also there were some macro economic goals of PTSE. These goals have been itemized in the letter of intent on 3rd of May in 2001 (Central Bank of Turkish Republic et al., 2002; Undersecretariat of Treasury et al., 2003):

- GDP will contract by 3% in 2001 and GNP will achieve growth by 5% in 2002
- The rate of CPI (Consumer Price Index) will be targeted to be 52% annually based on devaluation of TL (Turkish Lira)
- External current account will be in balance in 2001 and 2002 as a result of increased competition of Turkish products and downsizing in economic activity.

\$6.3 billion was demanded from IMF with the letter of intent dated on May 3<sup>rd</sup> 2001 after taking these measures. In 2002, Turkey demanded a new stand-by arrangement from IMF with the letter of intent dated on 18<sup>th</sup> of January 2002 to support economic stabilization program between 2002 and 2004. Strategy for the period 2002-2004 was prepared in the following format; In accordance with necessity for balance of payments and strengthened policies, approval of a new SBA including January, 2002 and December, 2004 with total 12,821.8 million SDR was demanded by Turkey. This program aims to guarantee the economy against future crisis and to create a non-inflationary and a sustainable growth (Undersecretariat of Treasury et al., 2002). Financial support provided from IMF by granting this letter of intent signed as a SBA on 4<sup>th</sup> of February in 2002. The measures in SBA are as follows:

- Implementing monetary policy to reduce until 35% and targeting 3% growth in the monetary base,
- To continue to apply the floating exchange rate regime that is the basic element for reducing inflation in monetary policy,
- Taking some measures for developing and deepening currency market and for expanding derivatives markets,
- Corresponding the financial goals with 6.5% of GNP in 2002,
- Taking new measures with the aim of supporting determined fiscal target for cutting spending and increasing income that is approximately 2% of GNP.

The decisiveness of implementation of economic program, adherence to fiscal discipline, continuation of structural reforms, the New Turkish Liras (YTL) being at a strong level and declines in interest rates has played a very important role in helping to continue the economic stability in 2005 just like the last three years. This steadiness reflected to the economic indicators and the number of individuals employed has reached 22 million people, growth rate in GNP grew to 7.6%, rising rate of Consumer Price Index (CPI) reduced to 7.7% and rising rate of Producer Price Index (PPI) declined to 2.7% and by remaining below expectations. As a result of this positive trend, Turkey's relations with IMF didn't halt in that period and Turkish Government re-signed a three-year 'Staff Monitoring Agreement' in May 2005.

The measures taken place within the scope of SBA signed in May 2005 are as follows:

- To continue the control of monetary aggregates and to get the amount of 6,662.04 million SDR of funds to be used in 12 equal slices on the basis of the balance of payments and financial framework,

- To increase resilience of economy to external shocks and to strengthen international reserve position for ending the usage of IMF resources (Undersecretariat of Treasury et al., 2005).

- To reduce the ratio of net public debt to GNP until 10 points by the end of the program.

- To keep under control the current account deficit by applying tight fiscal policies and to discover the resources needed for investment and growth.

However, with all these positive developments, Turkey was unable to cope with the current account deficit. TCMB, in 2005 intervened through direct purchases six times due to excessive exchange rate fluctuations in the foreign exchange market and the need for these interventions, as well as requirements of the current account deficit compared to the previous year, representing an increase of nearly 50%, increased to \$23 billion. In the face of such a situation programs implemented by the IMF for debiting an assumption that is formed, and as of May 2005 not to continue with the IMF, or at least that the termination of relations with the IMF in May 2008 there has been a large increase in discourse.

Such rhetoric of support in 2006 show a significant increase in the current account deficit increased to US\$32.5 billion at the end of the year and reached a level approaching 6% of the GDP. However, in 2006 like the other three-year period was a year where expected targets were not reached not only in terms of the current account deficit but also in terms of inflation rates. CPI inflation was 9.65% at the end of 2006, 11.6% in PPI inflation was realized, and by the end of the year, this rate is expected to remain well above the level of the upper limit of the uncertainty band. One can say that changes in the price of crude oil, processed food and gold all play a role in the rise of inflation. These negative factors experienced in 2006, as well as the unemployment rate, which was 10.3% in 2005 and declined to 9.9% as a thriving indicator. In general, Turkey's economy, through the period of 2002-2005 drew up a table far away from the rapid growth days; Turkey, within the framework of the IMF membership, as of December 31, 2006 quota, increased to SDR 1191.3 million with the conjunction of SDR 227.3 million on November 1, 2006, in a more blunt sense, the relationship with the IMF will be reflected in changes in the expression levels of macro-economic indicators achieved.

We have to consider that, during the first six months of 2007 compared to the same period last year, current account deficit has increased only 1.6% with the number of

\$23,5 billion (Ministry of Finance et al., 2007). Although, GNP increased slower compared to the last year (15%) by reaching \$277 billion; but also unemployment rate did not change (8.8%) and employment due to the rising in population surpassed over 23.5 million people. While these developments create a hopeful seen in Turkey, a global economic crisis broke out the world in 2008. However, despite the global crisis, Turkey did not sign the 20<sup>th</sup> Agreements with IMF as expected and continued to pay its debt. Turkey achieved to push back its debt to \$2.3 billion in March 2012 and \$400 million in the same period of 2013 compared to the end of 2002 with the number of \$23.5 billion. In fact, the government declared that it would pay back the entire amount of debt to IMF in April 2012, however interest rates were so low that the planned closure of the debt was decided to end in May 2013.

#### **4. Conclusion**

Countries, particularly in developing countries such as Turkey, which is in a deep economic crisis are in need of external support in order to ensure new economic stability. The IMF is one of the most important institutions that provide this type of external support. Turkey, to restabilize its deteriorated economic stability has implemented a total of seven IMF-Supported Stabilization Program since 1958. As discussed in periods of economic instability and the main objectives introduced for the elimination of both internal and external imbalances, was the practices of the stability programs, and the expected results could not be obtained.

IMF-type stabilization programs, which include elements of Heterodox and orthodox, when applied to countries to prevent a crisis or to get rid of the crisis, economic stability literally cannot be seen in these countries. The main criticism against the IMF in this regard is that the IMF does not look at the characteristics of the countries that have entered into a crisis, and proposes stabilization programs to each country has if they all have the same qualities. Turkey has had many bad experiences with the IMF-Supported Stabilization Programmes and one of the main causes of instability in the IMF programs is that it moves into action without looking at the realities of the country where the application of these new policies are proposed. However, the greatest criticism of the IMF after the 1995 crisis, is that instead of recovering the country of out the crisis, as an international lender it created a country on its way to fulfilling its debt obligations to banks and financial institutions.

With this widespread "bleeding" in Turkey, it forced people to think that it was time to terminate relations with the IMF. Pressure created by these ideas, thought of the "Staff Monitoring Agreement" which was created prior to the end of May 2008, in relation to negotiations with the IMF; the government had no opinion about what will happen with the future of our relations with the IMF, and when it came time for the government to make decisions it gave implicit explanations and tried to gloss over the issue. In fact, Turkey, with a new stand-by arrangement with the IMF set to continue for three years, and by itself can provide the ease of borrowing from the IMF. Because the last Strong Economy Transition Program revealed that economic stability is available in the country and proved to be the best out of the 19 stand-by agreements. Moreover, the IMF is willing to sit down at the table with Turkey. The reason for this, the IMF wants to catch a success with Turkey. However, Turkey knows all too well that in order to catch any more success it has to decline seating with the IMF and 20 agreements were planned in 2008, and Turkey did not sit at the

table. Indeed, Turkey decided to continue to pay its debts and by the year 2013, it proved to the world by show how much of a right choice it had taken.

Turkey - IMF relations in the framework of "stand-by" agreements have marked the last half-century of both the economic and political history has now come to an ending point. In its 51 year history Turkey signed 19 stand-by agreements, used \$46 billion 617 million dollars credit and with the interest paid a total of \$54 billion, 390 million.

As a result, Turkey is now determining the future of relations with the IMF, and is not planning to calculate the method of credit limits to be obtained. Correctly apply policies to stabilize the economy and to implement policies that are believed to be correct in order to protect from outside economic shocks; external credit support organizations such as the IMF will be engaged under conditions that are in favor of Turkey and in accordance with his own will.

Turkey having its current macroeconomic freedom is looking forward to developing its international trade area and it most likely will continue its relations with the IMF in a different form; not as a borrower but as a lender. It will give policy advise to the IMF rather than take advise. Turkey will be shown as an example by the IMF in terms of policies that helped development and recover Turkey's economy.

Turkey is one success case for the IMF but is it possible to repeat such a success? Are the policies of the IMF that were applied in Turkey applicable in other countries? Can the same results be achieved? The IMF will continue to monitor the successes and failures of its policies in Turkey very closely.

**Abstract:** *The paper presents a series of subsequent tools that provide the support for the complex tools regarding the important aspects of local and territorial development, such as strategic planning, sustainable development strategies, integrated development plans. The reference point of this research is represented by the management process in the public administration in the city of Baia Mare for which there are, in the general economy of the paper, the most complex resources for an empirical research. The Baia Mare Urban System presented in this paper has all the characteristics of a model structure of polycentric development that has elaborated/formulated a development overview on long and medium- term with all the strategic, tactical and operational elements that support the development within a well defined territory. The approach on both components (institutional, territorial) has a complex character but at the same time, a unitary one. The promotion of polycentric and balanced territorial development as an essential element for the territorial cohesion realization represents one of the priorities of Europe Strategy 2020. In this context, the formation and consolidation of the development poles as basic elements for the creation of polycentric networks must be supported by integrated politics at local and regional level. The study cases outlined in the paper represent models for the use of different public management tools in concrete situations that cover most of the fields approached in local administration.*

**Keywords:** *sustainable development, Europe Strategy, urban system*

**JEL classification:** *J11, R11, R23.*

### **1. Introduction**

The approach of the European Union has evolved from the social dimension to the competitive one (Lisbon Agenda, Leipzig Carta, European Territorial Agenda) thinking at a larger scale (metropolitan scale, growth poles). Following this, the present article wishes to provide a practical framework which can be used to better understand the need of an efficient urban system and, also, to create an urban system based on competitiveness and innovation.

Allocated to each strategic objective, according to the locally established strategic planning, policies of sustaining the promotion of public programs have been defined, concerning development in urban, over or suburban context in Baia Mare city.

The territorial adjustments in the field of economy and housing, the conservation and the promotion of natural values, the development of the basic public infrastructure are some of the major fields of interest.

A number of issues defining the urban system management Baia Mare emerged from the diagnosis analysis carried out. This set of problems will lead us, as a next step, to formulate strategic objectives and policies, programs and development projects, respectively:

- the peripheral position in relation to the major transportation corridors;
- the effect of economic restructuring;
- the existence of regional disparities;
- the existence of environmental issues;
- the damaged built heritage;
- the complexity of public management.

Considering the elements that are part of the vision of development, the strategic objectives for which the Baia Mare Urban System Association has been created are: improving the quality of life and removing the existing disparities between localities, creating a pole of economic concentration and support for attracting investment and for further development of jobs in this area. 18 policies have been established in order to implement the development strategy of the Baia Mare Urban System, accompanied by a series of measures and concrete projects which are necessary for its implementation.

## **2. The implementation of a Strategy for Local Sustainable Development**

Starting from the assumption that there exist administrative-territorial entities, respectively the commune/ the town/ the municipality, a first instrument of strategic management was identified through the drawing and the implementation of a Strategy for Local Sustainable Development. The case study taken into account is the local Agenda 21 and all the data and the specific measurement instruments used in this case study were collected through the systematic analysis and evaluation of the economic development in the Baia Mare urban and suburban area.

The sustainable development of the Baia Mare municipality through Agenda 21, which contains the elements of both a development strategy and of a transformation strategy, is characteristic of a pro-active community development. One crucial element which led to its elaboration is represented by the existence of a well-developed community, with a positive potential of human resources, within the context of a radical change in the fields of activity in the local economic sector.

The necessary equilibrium for implementing such a strategy is sustained through the achievement of an efficient communication with the local community in order to directly involve it in the process of decision making and the promoting of measures necessary for implementation, as well as through the over-development of the tactical level, able to sustain the reaching of medium and long-term goals within strong social and economic transformations.

The way of integrating the local strategic objectives at a county and regional level has been realized through the promoting of an ascendant strategic construction ("bottom up"), the elements of the local strategy being the basis for the construction of strategies at county and regional levels.

Steadily promoting the objectives and measures established by Agenda 21, both at a formal and an informal level, Baia Mare has succeeded to make known and to

render assimilated at county and regional levels through the specific strategic documents all the elements of the local sustainable development strategy, thus influencing the county and regional concepts of development.

Implementing the strategy represents the practical stage of planning and monitoring the process of putting into practice the decisions expressed in development programmes and projects. This must ensure the reaching of the strategic goals that have been stipulated, through the implementation of projects at the community level (Applen, 2002; Benson *et al.*, 2004).

The Sustainable development strategy represents a strong political pledge on the vision about the future of the community and at the same time a platform for the coordination of integrated actions from the urban agenda assumed by the collectivity. The strategy answers the challenges with which communities are faced on a global scale: financial crisis, competitiveness and globalization, a decrease in population and the demographic aging, migrations, climatic changes and the management of energy resources, to which are added, at an internal level, the process of decentralization in the education and health systems (Choo & Bontis, 2002).

Through the experiences encountered by the municipality of Baia Mare during this implementing period, the perspective of a supra-urban level depending on the global agglomeration that had created it was identified, the necessity of development being in this respect approached from a territorial point of view. The modification in the ratio of resources between the dense urban zone and the adjacent rural zones is analysed according to the common values and objectives they sustain.

To this purpose the concept of poly-centric regional development has been analysed and developed, the great urban centers having a polarizing role for the adjacent influence zone. The Metropolitan Development Strategies represent the third instrument of strategic public management dealt with within this paper. The case study and the functional links between the urban pole and the influence zone have been developed and analysed in the case of the Baia Mare Urban System.

This poly-functional territory has been analysed both from the perspective of defining the administrative limits and from the point of view of the social, economic and environmental development potential. The defining of a metropolitan-type strategy, as well as of some afferent measure plans needs an institutional and financial construction in order to efficiently complete the territorial dimension.

The approach of the Sustainable Development Strategy of Baia Mare city has as its foundation the global and European experience in the domain of strategic territorial planning, within the context of promoting

The territorial development knows a new approach within which the social, economic and territorial dimensions are treated in an integrated manner in the context of the sustainable development. The decisions regarding measures for development are made under multiple pressures, and the phenomena that manifest themselves locally have an ever-growing territorial dynamics.

Romania's development is based on a powerful system of major development poles connected to the complemented system of support specialized poles by a good partnership relation between the different levels in view to ensure the socio-economic and territorial cohesion, the sustainable development.

In this context it is necessary to consolidate a coherent network of development centres which is to act as development engines, and also as an equilibrium structure at the regional level in Romania.

The Urban System Baia Mare is a functional example of territorial structure which has drawn a development strategy where there have been underlined the key-aspects of management, the strategic objectives, the policies and the development measures.

The instruments used have mainly been those promoted by the local public administration, these having the role of offering consistency to the private and public policies at the level of local or regional communities. The decisive role of public management in the near future is to build the “frame” for the social and economic development of a well defined space.

This space must tackle with both the values of local identity (cultural, economic, social or natural environment), and the major challenges linked to globalization-related phenomena, the ever-changing world economy and the degrading of the environment.

The instruments of public management facilitate the access of the community, in its whole, to public resources and the development vision of a community, the public administration playing the major role of managing these resources for a rise in life-quality levels within the community it represents.

The use of the Baia Mare model as a good practice example and the improvement of public management tools in the context of innovative approaches through the involvement of the local community and of the strategic partners forming a genuine partnership for the development of policies and actions.

Dissemination of the local experiences outlined in this paper regarding the integrated development gathered through the activities performed by associative structures (urban agglomerations, metropolitan areas, local action groups, community development associations) and consolidation of all local initiatives with respect to sustainable development and applying for and use of resources from European funds.

Connection to the European network (URBACT) dealing with the strategic management for land use, which is considered to be the most important tool for the approach and provision of competitiveness, attractiveness and sustainability of European cities/regions. This implies an approach at the strategic level (planning instruments, observation instruments), as well as at tactic and operational level (action plans, study cases) and it can generate a series of practical models and methods for similar communities interested in local development.

Drawing up new grounds that would settle the objectives and criteria based on which new partnerships will be built between regional or local governments and all the economic, social stakeholders, with structures that represent the civil society, with non-governmental organizations or other bodies interested in the sustainable development of communities.

Enforce the indispensability according to which the strategic and urban plans for large cities are elaborated and approved in accordance with those of the adjacent administrative divisions.

In order to approach the proposed objectives, we will present hereafter several proposals that would allow a professional approach of the issues related to integrated local development (Anghel, 2013):

- Creation of a participative framework, involving all the categories of local stakeholders in the decision-making process with respect to the sustainable development of the communities they are part of. Besides local authorities, representatives of the public sector, including decentralized institutions,

private entrepreneurs, professional associations, education or research institutions, unions, non-governmental organizations or other representative of the civil society should be involved.

- Development of local networks and partnerships for the use of the participative mechanism correlated with an efficient information and communication system, which will further allow the concentration of resources and the optimal exploitation of the local potential.
- Elaboration of three types of main tools meant to orient and promote a realistic and responsible vision upon the local development perspectives: a local development strategy that sets the medium and long- term objectives; an action plan that outlines the priorities and steps to be taken on medium and long - term for reaching the objectives set in the strategy, that will include cost assessment, identification of financial resources and how to apply for them; a portfolio of projects considered by the entire community as priorities for the sustainable development of the city or region.
- Completing the legal background for the integration of the strategic vision regarding spatial planning and city planning in the local and regional development programmes. Institutional and administrative capacity-building in local governments in order to elaborate the strategic development documents for each locality (Local Agenda 21, sustainable development strategy, integrated plans, portfolio of projects).
- Setting up a clear calendar for the preparation, elaboration and correlation of the strategic documents, of the mechanisms and related tools, necessary to apply for European funds foreseen for 2014- 2020, in order to be able to reach the objectives set by the European Strategy 2020 and by the national programmes (National Reference Programme, National Development Plan, Operational Programmes).

The case studies presented in the paper may represent models of good practice for any city hall in Romania as regards the increase of institutional and administrative capacity at the level of local authorities and civil societies, the management of polycentric territorial-administrative development

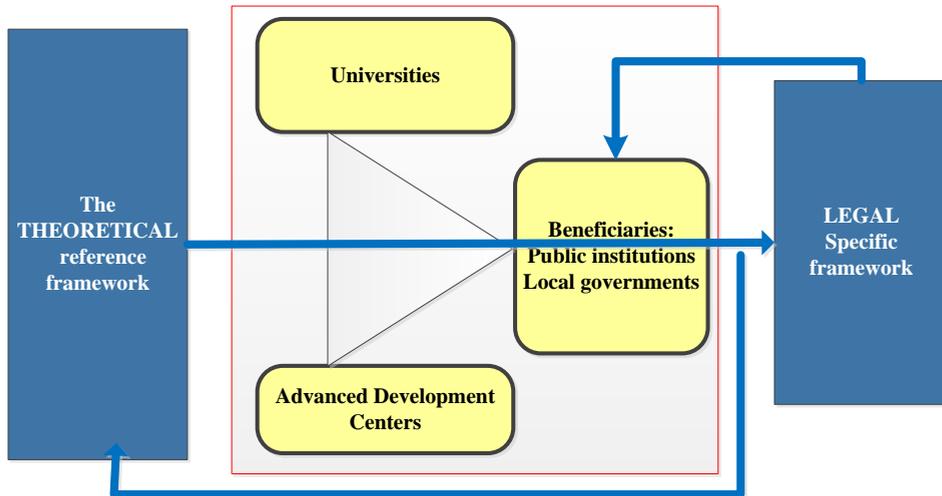

For the implementation of politicise related to the integrated polycentric development network, instruments specific to the territorial spatial planning (investment programs, territorial plans, monitoring of territorial development), non-spatial (budget, finances, administrative capacity) and strategic planning (strategies of regional development, coordination mechanisms, politics substantivise, strategic planning) are used.

The promotion of polycentric and balanced territorial development as an essential element for the territorial cohesion realization represents one of the priorities of Europe Strategy 2020. In this context, the formation and consolidation of the development poles as basic elements for the creation of polycentric networks must be supported by integrated politics at local and regional level.

This public institutional construction precedes and becomes an a priori condition regarding the success of an administratively-territorial durable development process (at the level of neighbourhoods, belonging localities) as well as at territorial level of a superior rank: microregional, county and regional.

The tactic direction of the public management modernization process. In all planning documents of the development at national level, the collocation “The triangle of knowledge” is used especially within the field of “Growth of Economic Competitiveness”. The collocation symbolically presents the importance of the

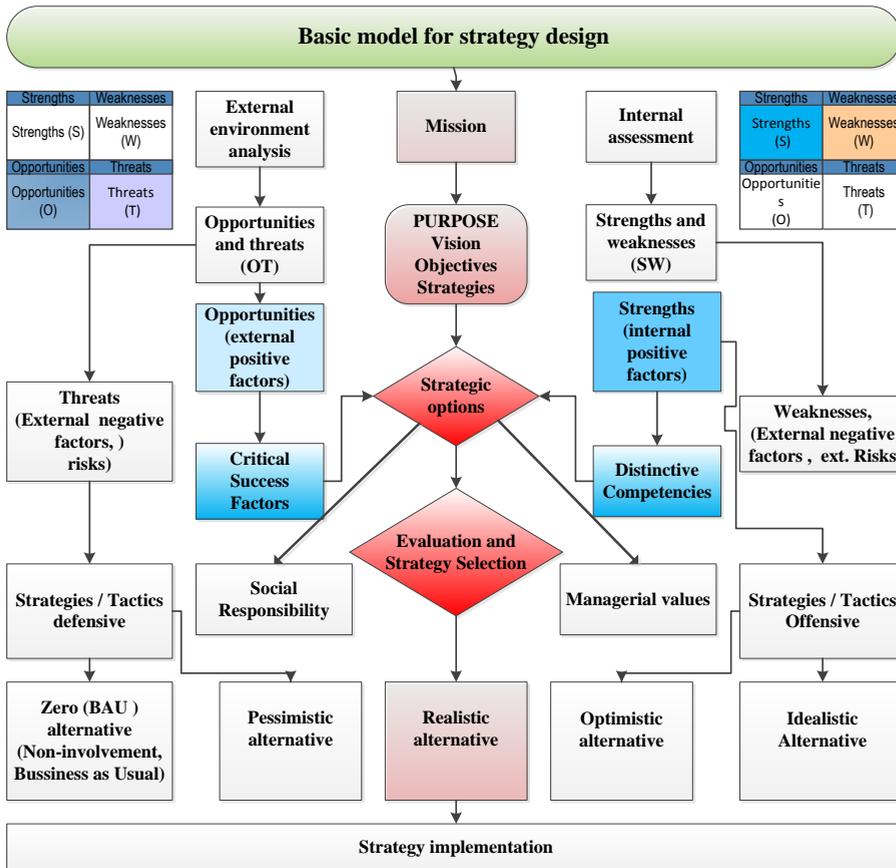

relationship between: (1) Universities (assimilated with fundamental research centres, (2) Development Innovation Centres (CDI – assimilated with platforms of applicative research, initiators of “pilot” projects, consultancy providers or facilitators of technology transfer) and (3) Enterprises, in order to ensure the competitive advantages on long -term period of some products or services.

**Figure 1:** The development process of public management  
Source: Anghel, 2013

The development process of public management based on the application of “The triangle of knowledge” presents the following advantages (Anghel, 2013; Anghel, 2006):

- It uses the advanced research (on long- term) and the theoretical foundation of the modernization instruments construction of the public administration ensured by the “university” partner.
- It ensures the optimizing process and efficiency of the construction and practical application (adaptation to the beneficiary’s specific) of the public management instruments, ensured by CDI specialised in different fields: Technology of Information and Communication, Human Resources, Public Relations, Public Politics, Financial Management);
- It represents an answer given by de practical application of the public management instrument that shall lead to the evolution of the theoretical frame of public management, ensuring its continuous development and adaptation to the modifications of public institutional environment from Romania;
- It contributes to the creation of a legislative frame adapted to real needs, tested by the national public system and not based on prognoses or opinions of an expert type;
- It allows the facilitation of a legislative frame whose norms were pre-tested by pilot projects and agreed on by beneficiaries.

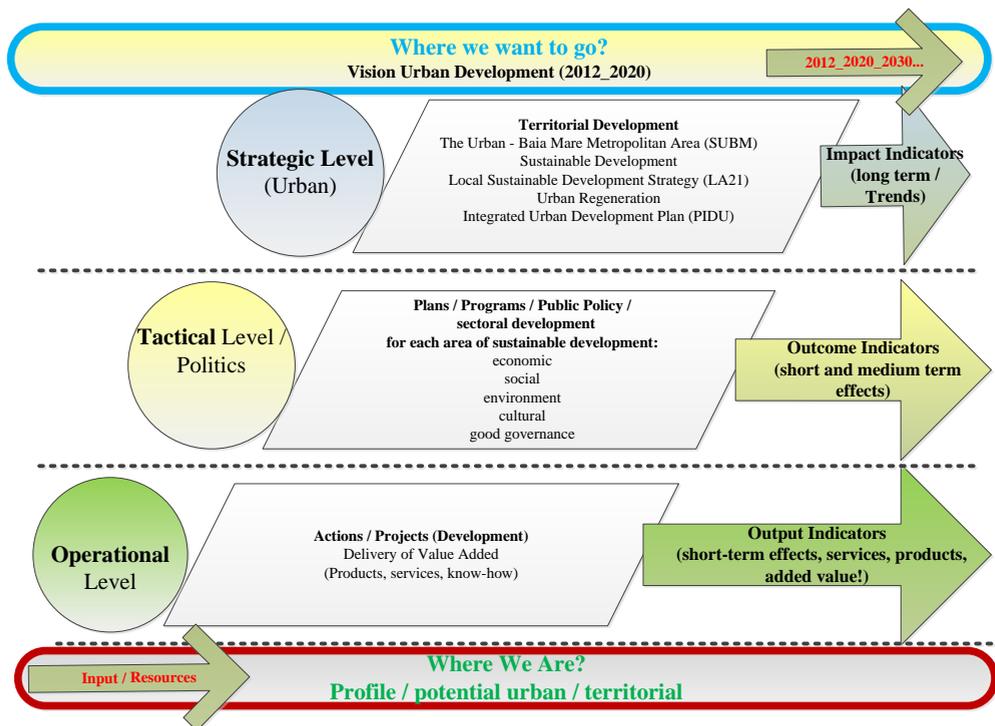

**Figure 2:** Model for strategy elaboration  
Source: Anghel, 2013

The base model used for the formulation of the strategy was used in all phases of the measurements, starting from a simplified model with approaches on two directions represented by the SWOT analysis part (analytical approach), respectively the visionary measurements (overview, mission, strategic targets). The two approaches have finally generated five types of strategic alternatives (zero alternative, pessimistic alternative, optimistic alternative, realistic and visionary alternative)

The model emphasizes the two great types of approaches (defensive and offensive) important especially in tactical phases that aim at medium- term targets.

Another advantage of the model is the emphasis and picture of the distinctive competitiveness and competent elements as critical factors of success, respectively the social responsibility and managerial values as important elements within the complete

**Figure 3:** Concept of Local – Territorial Integrated Development  
Source: Anghel, 2013

A series of public management instruments are interconnected in order to realise a unitary construction that covers the entire problematical aspects of a community at a county capital city level.

The Scheme of the Local-Territorial Development Concept synthetically presents:

(a) The content of the stages of local-territorial development planning:

- Definition of urban – territorial profile based on the quantitative indicators (statistics) and the qualitative indicators of the local resource types (natural, physical, human, social and financial);
- Evaluation of the development potential (based on the strategic analyses SWOT/PEST of the local – territorial profile);
- Establishment of strategic planning elements;
- Definition of the development overview, an ideal image of a desirable future, shared within the community;
- Establishment of development targets and measures (strategies and programmes)

From the territorial perspective of the administrative unit (subunits – neighbourhoods, or supra-units– territorial cooperation areas; microregional, counties, regional);

- From the sectorial field perspective of the local development integrated within the concept of durable development (economic, social, environment, culture, governing)

(b) The process of local-territorial planning, definitive for the local capacity evaluation of public management. It is defined through the involvement degree (civic participation) of all concerned parties in all planning stages (by information, consulting, participation ), ensuring the participative character of the elaboration, public assumption and application of local-territorial development politics.

(c) The levels and types of indicators of the monitoring and evaluation system of the implementation progress of development elements:

- Impact indicators (long- term effects on big groups of beneficiaries, the entire community), definitive for the degree of achievement of strategic objectives;
- Result indicators (short- term effects on some specific target groups) that define the degree of the achievement of the programmes, applied plans, respectively of the specific objectives and planned measures;
- Exit indicators/“output” (services and products realised as a result of projects’ application, services provided within the Local - Territorial Action Plan)

### **3. Conclusion**

The sustainable development strategy of the Baia Mare city defines the general frame in what the decision-making process in urban planning is concerned. It is a comprehensive document which defines the Urban Agenda for Baia Mare, putting together visions, projects and opportunities with a particular stress on sustainable options. It offers solutions for development creating a sound basis for the future of the city as well as a frame for a better use of structural funds.

In the process of drawing the sustainable development strategy of the Baia Mare municipality there has been used for the first time in Romania the poster-plan type of cartography, which presents the main strategic choices until 2020. It is a synoptic document which projects the future of the community, a perspective document which puts into the limelight both the conceptual axes of the city’s development and the zones envisaged for intervention within the following years. ( zones of urban development, zones of urban regeneration).

My recommendation refers to the extrapolation of this collocation at the level of public management by the promotion and support of a development process of public management at national and local level based on the collocation named “The Triangle of knowledge”, that emphasizes the partnership relationships that must be built at the level of a community, with extended possibilities at territorial level.

Thus, a useful co-operation between the fundamental actors of the community that must participate in formulating the development overview and the elaboration and implementation of all fundamental documents that contribute to the increase of local capacity of development is achieved.

The development of the management capacity of local public administration institutions requires the use of some modern management instruments that shall lead to an increase of the administrative capacity at local level.

The case studies presented in the paper may represent models of good practice for any city hall in Romania as regards the increase of institutional and administrative capacity at the level of local authorities and civil societies.

For the implementation of politicise related to the integrated polycentric development network, instruments specific to the territorial spatial planning (investment programs, territorial plans, monitoring of territorial development), non-spatial (budget, finances,

administrative capacity) and strategic planning (strategies of regional development, coordination mechanisms, politics substantivise, strategic planning) are used.

The promotion of polycentric and balanced territorial development as an essential element for the territorial cohesion realization represents one of the priorities of Europe Strategy 2020. In this context, the formation and consolidation of the development poles as basic elements for the creation of polycentric networks must be supported by integrated politics at local and regional level.

The Baia Mare Urban System presented in this paper has all the characteristics of a model structure of polycentric development that has elaborated/formulated a development overview on long and medium- term with all the strategic, tactical and operational elements that support the development within a well defined territory.

**Abstract:** *This paper intends to understand the major institutional factors related to the economic development of the European Union (EU) countries in the last two decades. It provides some contributions to the institutionalist debate of the present crisis of the European Union, and within it, the Economic and Monetary Union (EMU). The two main issues of the empirical research are the effect of the different institutions on economic growth and the relative importance of institutions compared with the traditional macroeconomic components of economic development. The institutionalist traditions of comparative political science and political economy as well as institutional economics define the framework of interpretation. The analysis sheds some light on the relationship between economic development and the different institutional dimensions, namely the legal environment, political institutions, public policy institutions (governance) and the informal institutions, the cultural components of the economic-political behaviour. The empirical research examines the development pattern of the European Union countries between 1993 and 2011 as well as the relationship between economic development and institutional quality in that period by descriptive and explanatory statistical methods. The results reveal strong relationship among the different aspects of institutional quality in the EU countries; within Europe we cannot observe a Singaporean type contradictory constellation between the quality of democratic institutions and public policy effectiveness. The path of European development has been drawing a conspicuously strong correlation among the different institutional dimensions: the high quality of democratic institutions, the respect of the rule of law and property rights and the effective governance are going hand in hand with the growth-supporting components of the culture. In cultural terms, the high level of trust, respect and self-determination as well as the lack of obedience ensure the most successful long-term growth pattern in Europe. Another important finding is that the EMU countries are conspicuously heterogeneous in their institutional quality and the Mediterranean members of the Euro area are institutionally closer to the non-EMU-member Central-Eastern European countries than the core EMU countries. Concerning the economic policy consequences, the heterogeneity of the informal institutions fundamentally challenges the effectiveness of the approach of stronger harmonisation by stricter formal rules and stricter sanctions against the norm-breaking Euro area members.*

## **1. Introduction**

The European Union (EU) is in deep crisis; at the moment there is no serious professional or internationally respected public figure who can debate it. In mere economic sense it is obvious that the global financial crisis has implied a debt crisis and a subsequent long-lasting recession in several countries of the EU. At the beginning of 2013 it seems that the European Union as an actor in itself has more difficulties in managing the crisis than other developed regions of the world. Moreover, it is already doubtful whether the EU, and within it especially the group of the countries using the common currency, the Euro (the Economic and Monetary Union, EMU) will be able to survive this crisis without losing some of its members. Indeed, the EMU (and also the entire EU) is seriously endangered as a political construction, at least in its present form (Habermas 2012).

Most of the policy suggestions presented as 'solutions' of the present crisis explicitly or implicitly derive from the diagnosis that the problem is ultimately the weakness of fiscal federalism in Europe. Briefly, the mainstream approach is that the Eurozone can be saved only if decision-making is federalized (Darvas 2010); the efficient management of the present crisis of the EMU requires stricter rules as well as stricter sanctions against the norm-breaking countries (Hodson 2012). It is noteworthy that even those who debate this therapy accept the 'federalism problem': the typical counter-arguments point to the problems of legitimacy of the EU institutions, the contradictory nature of sovereignty within the EU, and the problems of the European identity, the lack of a European 'demos' (Cederman 2001, Schimmelfennig 2010). But these problems have already been well-debated several times, among others, nine years ago when a big-bang enlargement happened (see the overview of Körösenyi, 2004 about that). Logically, the absence of a strong common European identity implies a relatively weak solidarity potential towards other EU nations: the willingness of support for bailout purposes in a time of an enduring crisis is moderate – incomparable for example with the quasi-automatic solidarity of West-German citizens and politicians towards East-Germany in the decade after the German reunification (Dochartaigh 2010).

In this paper I intend to open the black-box of the European institutions. By stepping out from the federalism debate frame, I interpret the development of the European economies in the last two decades from a deeper institutionalist perspective that integrate the recent theoretical and empirical findings of new institutionalism in political science as well as in comparative macroeconomics.

The next section briefly deals with the potentially relevant institutional approaches in the context of the EU countries' development. Section 3 analyzes empirically the economic and institutional development of the EU and EMU countries between 1993 and 2011. The final section presents the concluding remarks and discussion.

## **2. Institutional development and economic growth**

The institutionalist perspective has recently become integrated in the main streams of the different social sciences. In the political science the expansion of new institutionalism started in the eighties (Peters, 2005:16). In organisational sociology, the revival of the 'embeddedness' approach of Polányi (1957) in the seminal paper of Granovetter (1985) implied a culturalist research perspective: the role of values and norms in the working of organisations became a new research programme in the nineties (DiMaggio, 1990). Moreover, the institutionalist approach is obviously

important in economics as it was already part of the classical school (Smith, 1899[1776]). However, the specific institutional explanations of the basic question of growth theory (why some countries are rich and why are others poor), has only come back into the mainstream in the last two or three decades when the new growth theory approach integrated the major results of institutionalist economics (Helpman 2004, Czeglédi 2006).

### **2.1. Growth and institutional quality in the European Union**

The European Union and especially the Economic and Monetary Union as one of its enhanced institutionalist cooperation projects has followed the logic of pro-active institution-building: the less developed countries of the community are supposed to incorporate the 'good' formal institutions of the most developed ones. Theoretically the EU and again, especially the EMU is supposed to be a convergence club (Baumol, 1986): the criteria of entrance select among the aspirants, and the applied new rules and organisations (in terms of North 1990: the formal institutions) will help the less developed countries to gradually converge towards the more developed ones. However, the imitation of the 'best' formal institutions has not necessarily implied a convergence in economic development. In this context, the literature suggests four potential institutional factors of economic development (Bartha, 2012): (a) the legal institutions, (b) the political institutions, (c) the institutions of governance (professional bureaucracy, public policy expertise) and (d) the informal institutions (values and norms orienting the behaviour of political and economic actors).

### **2.2. Research questions and hypothesis**

This paper attempts to answer two main questions: (1) What is the effect of the different institutions on economic growth in the EU and the EMU countries? (2) What are the relative importance of the different types of institutions compared to each other and the traditional macroeconomic variables? The hypothesis to be tested here is the following: as the last two decades of the European development was characterized by an increasing convergence in the formal (legal and political) institutions, the stubborn differences in economic development levels are mainly caused by the differences in informal institutions and governance.

## **3. Empirical research**

### **3.1. Variables, operationalization**

The growth accounting framework is the starting point for the empirical research; namely the augmented Solow model (Mankiw et al. 1992:408) that among the explanatory variables of growth includes the accumulation of human capital as well (in addition to physical capital and labour). In this context, the role of institutions is reflected by the unobserved total factor productivity (TFP), as a country's total factor productivity 'is a function of the country's policies and institutions' (Parente 2001:56). Consequently, the different (legal, political, policy and cultural) institutional approaches are rival specifications of the TFP residual in the growth accounting.

#### **3.1.1. Dependent variable**

The dependent variable chosen for this research is economic growth. The indicator is the change in GDP per capita in Purchasing Power Parity between 1993 and 2011.

The source of these data (as also for other macroeconomic data) is the Penn World Table 7.0 (Heston et al., 2011) database for 1993-2009; the values for 2009-2011 are extrapolations based on Eurostat data.

### 3.1.2. Independent variables

#### Macroeconomic variables

The independent variables are specified in the framework of conditional convergence (Barro- Sala-i-Martin, 1992:226). The first independent variable is the *level of economic development (GDP per capita in Purchasing Power Parity) in 1993*. If the quality of institutions does not play a major role in long-term economic growth, this variable basically defines the trends: the poorer countries should gradually but steadily converge towards the most developed ones.

The next independent variable is the *change in physical capital*; the proxy of it, following the international practice, is the investment/GDP ratio. The *change of labour* is measured by the average change in the number of people employed, the technological change and the amortisation (a negligible factor in the present analysis) are supposed to be 0.05 (an international convention since the seminal paper of Mankiw et al., 1992).

I have used a less conventional indicator for the proxy of *human capital investment*. Among others, van Leeuwen and Földvári (2008) revealed that when we compare the EU countries, the use of the conventional 'average years of education' proxy overvalues the human capital of the Central-Eastern European countries. Therefore I have applied as a proxy of human capital investment the indicator of 'cognitive skills' developed by Hanushek and Woessmann (2009), although with some modification. Their 'cognitive skills' indicator is derived from the OECD Programme for International Student Assessment (PISA) survey: cognitive skills are "measured by the simple average of all observed math and science scores between 1964 and 2003 for each country" (Hanushek and Woessmann, 2009:8), it is probably biased somewhat against the literacy skills. Consequently, I have also included the simple average of all observed literacy skills scores; this 'cognitive and literacy skills' is the proxy of human capital investment used for each of the European countries.

#### Institutional variables

I have operationalized four different institutional type variables from different international surveys. The proxy of the Northian *formal institutions* is the sub-index of Legal Structure and Security of Property Rights from the 2011 Annual Report of the Economic Freedom of the World from the Cato Institute (Gwartney et al., 2011). The proxy of the Northian *informal institutions*, i.e. the cultural components guiding the behaviour of the economic and political actors comes from the 'culture' principal component of Williamson and Mathers (2010). The authors constructed the values of this culture principal component from the different data collection waves of the World Values Survey; according to their interpretation, trust, self-determination and respect are positive correlates of the economic development, while the obedience is a negative component of that. The proxy of the quality of democracy, the quality of *political institutions* comes from the democracy index of the Economist Intelligence Unit. This index involves the quality aspect of the democracy (Ringen, 2011); in addition, we have values for all of the EU member states for several measurement periods. Finally, the proxy of the *governance*, the quality of expert-bureaucratic

institutions comes from the World Bank “Worldwide Governance Indicators (WGI)” project (Kauffmann et al., 2010) the sub-index of government efficiency was selected for this. By using long-term average values for all of the four institutional proxies I followed the international conventions.

### 3.2. Main findings

#### 3.2.1. Institutional relations between legal institutions, democracy, governance and culture

The comparison of the relative standard deviations (see Table 1) supports our hypothesis: among the 26 European Union member countries, the most important differences can be registered in the informal institutions. However, the smallest differences are in the quality of democracy, while in the legal institutions and the quality of governance we find more significant differences (but less significant ones than in the dimension of culture).

**Table 1: The heterogeneity of institutional indicators**

	LEGAL	CULTURE	GOVERN	DEMOC
Standard deviation	1.18	1.80	12.99	0.79
Means	7.32	5.24	73.50	8.06
Relative standard deviation	16.15	34.34	17.68	9.75

Sources: LEGAL (Legal Structure and Security of Property Rights): Cato Institute, Gwartney et al., 2011; CULTURE: Williamson and Mathers (2010); GOVERN (Government Effectiveness): World Bank “Worldwide Governance Indicators (WGI)” project (Kauffmann et al., 2010); DEMOC (Democracy), Economist Intelligence Unit Democracy Index

Nevertheless, it would be misleading to draw a conclusion of ‘incompatibility’ between democracy and culture in the EU. The correlation matrix of the four institutional variables reveal a strong relationship: the bi-variate correlation is significant at a 0.01 probability level between each of the four variables.

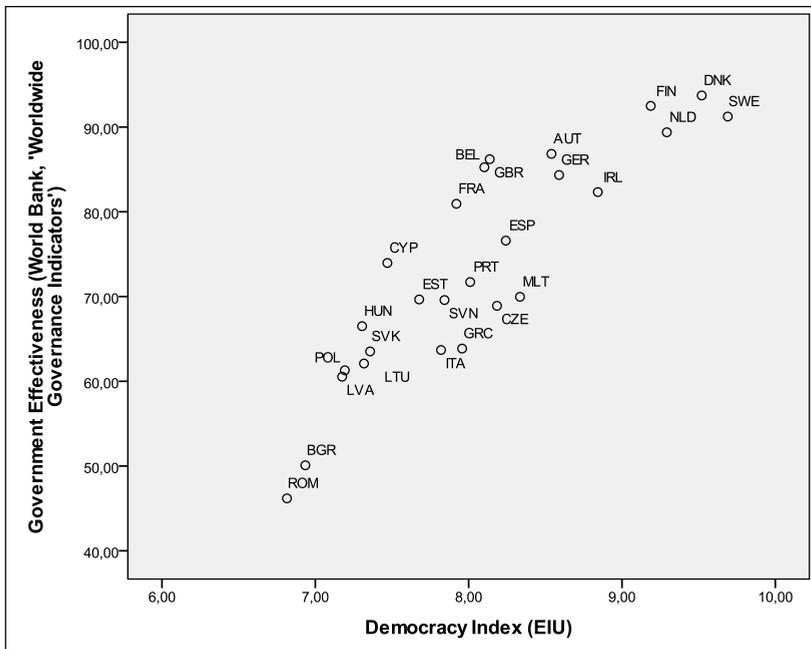

**Table 2: Correlation between institutional factors**

	LEGAL	CULTURE	GOVERN	DEMOC
LEGAL	1.00	0.72	0.93	0.86
CULTURE	0.72	1.00	0.69	0.82
GOVERN	0.93	0.69	1.00	0.89
DEMOC	0.86	0.82	0.89	1.00

Sources: LEGAL (Legal Structure and Security of Property Rights): Cato Institute, Gwartney et al., 2011; CULTURE: Williamson and Mathers (2010); GOVERN (Government Effectiveness): World Bank “Worldwide Governance Indicators (WGI)” project (Kauffmann et al., 2010); DEMOC (Democracy), Economist Intelligence Unit Democracy Index

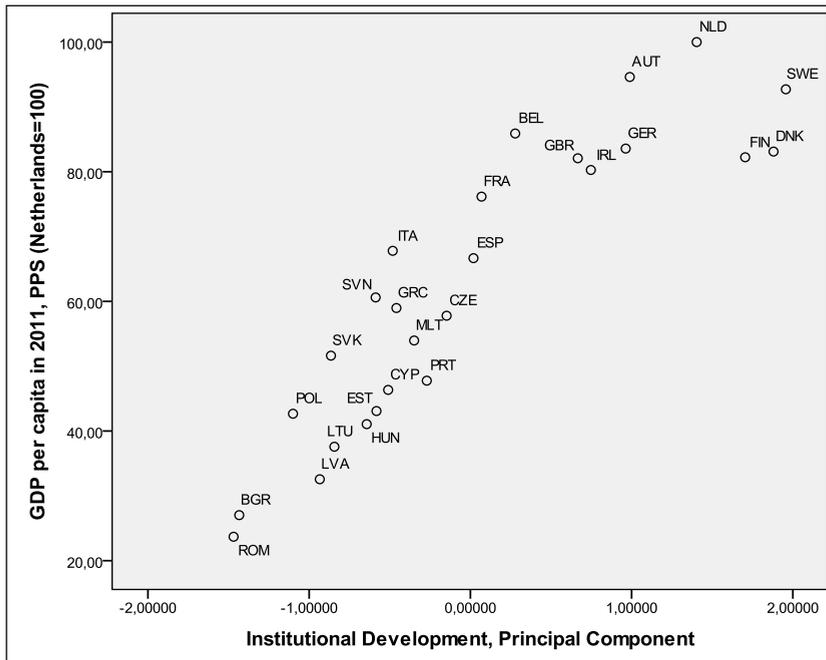

The quality of democracy correlates strongly with all of the three other dimensions, but the strongest statistical relationship (93%!) can be registered between the government effectiveness and the legal structure. These findings indicate that the

Lee-thesis, the assumed Singaporean type contradiction between democracy and government effectiveness is not valid in the EU on the long-run (for more criticism about the Lee-thesis see: Knutsen, 2010); either the quality of democracy or the government effectiveness is the strongest in the Nordic countries, while Bulgaria and Romania are the laggards in both aspects (see Figure 1).

**Figure 1:** Quality of democracy and government effectiveness in the EU  
Sources: Economist Intelligence Unit and the World Bank

Consequently, it requires a specific methodological treatment to minimize the obvious endogeneity and multicollinearity problems: we have to include a common factor of institutional development in our explanatory models (and not four different institutional variables). The principal component analysis derives one principal component from the four institutional dimensions that explain 86.5% of the variance of the original institutional variables. The strong relationship between this constructed institutional development component and the economic development level supports our interpretation about the underlying institutional factors behind the seemingly economic problems of the European integration. Figure 2 regarding the EU member countries' economic and institutional development obviously indicates that the Economic and Monetary Union is not the club of the most developed European countries; neither in economic, nor in institutional development terms. Not only because the institutionally two most developed countries of the EU (Sweden and Denmark) are not members of the EMU, but also because of the apparent weaknesses of the Mediterranean countries' institutions.

**Figure 2:** Institutional and economic development in the European Union  
Sources: Penn World Table 7.0 and calculations by author

Among other things, our institutional data indicate that one founding member, Italy is more like the two countries that joined the EU only five years ago (Bulgaria and Romania), than Sweden (the institutionally most developed EU member). It is also noteworthy that the institutional development level of France is only around the EU average and it is significantly weaker than that of Germany; paradoxically, in addition to Austria, the institutional development level of Germany is the closest to that of Ireland and the United Kingdom. Though there are several arguments that multiple development clubs are forming within the EU in the spirit of differentiated integration (Koller, 2012), it is doubtful that the EMU can be considered an outstanding development club of enhanced financial cooperation. This is not true in economic terms; it is even less true in institutional development terms. Moreover, because neither the Czech Republic, nor the United Kingdom are EMU members, it is not even true that the common currency area concentrates the EU average countries in economic and institutional development terms.

The hierarchical clustering process of the institutional dimensions draws three sub-groups among the more developed EU countries: the three Nordic states and the Netherlands form the group of the most developed countries; Germany, Austria, Ireland and the United Kingdom constitute a second group, while France, Belgium and Spain are on the margin of the more developed EU countries. The institutionally less developed Southern and Eastern EU member countries are positioned along a continuum; only Bulgaria and Romania form a separate cluster.

### **3.2.2. Economic development: institutional and other explanations**

I would like to reflect briefly on the weight of institutional and other explanations in economic development. Though the initial development level (in this analysis in 1993) correlates significantly and negatively with the economic growth in the last two decades, the moderate value of the determination coefficient (0.58) conforms with our expectations, that is, the more refined explanations can have empirical relevance in the development of the EU countries. The inclusion of our institutional development principal component significantly increases the explanatory force: in this model the value of the adjusted  $R^2$  is 0.65. However, in a technical sense, our institutionalist explanation is weaker than the human-capital-augmented Solow model (the adjusted  $R^2$  increases to 0.76). Indeed, the human capital seems to be the decisive factor (besides the initial development differences). Nevertheless, this does not mean that we have to neglect the institutional effects in interpreting the economic development of the EU countries; the novelty of our human capital investment proxy is precisely the inclusion of the labour market adaptability dimension in the educational variable that means an implicit incorporation of the institutions, especially the informal institutions.

## **4. Conclusion and discussion**

This paper presented an institutional, comparative political economy perspective for the EU countries' growth patterns; it also offered the institutional heterogeneity thesis in framing the enduring crisis of the EU and the Economic and Monetary Union. Four potential institutional explanations of long-term growth were operationalized: the formal institutions by the legal structure, the Northian informal institutions by the cultural components guiding the behaviour of actors, the political institutions by the quality of democracy, and the bureaucratic-expert institutions by the quality of governance.

The expectation of the empirical research was that the formal institutional resemblance of the EU and especially the EMU countries is in sharp contrast with the stubborn and significant differences along the dimensions of the governance and the cultural components. However, the empirical findings are not undoubtedly supporting this hypothesis. In fact, the path of European development draws a strong correlation among the different institutional dimensions: the high quality of democratic institutions, the good legal structure, the efficient government and the supporting components of culture (trust, respect and self-determination and the lack of obedience) are going hand in hand.

This implies that the present crisis of the Eurozone is not mainly economic in nature, and it is not predominantly the problem of the supposed bad governance of the South-European political elites. The root of the political crisis comes from the much deeper institutional heterogeneity; concerning their institutions, the older Southern EU member states are much more like the new Eastern-Central EU member countries than the institutionally most developed Nordic ones. Because of the endogenous nature of this institutional heterogeneity, the stricter rules and the stricter sanctions against the norm-breaking countries are unlikely to solve the crisis and preserve the survival of the Eurozone in its present form. The best case scenario is a slow, gradual convergence when the constant human capital improvement of the less developed EU and EMU countries imply a self-reinforcing improvement in the legal and political institutions, governance and the cultural components guiding the behavioural patterns of economic and political actors.

Why can we observe these conspicuously strong relations between the different institutional aspects in Europe in the last two decades? One possible explanation derives from the global interconnectedness, the increased role of perception of the global financial and capital markets. Practically all of the EU member countries depend basically on the external perception, but they depend independently (and not together as the EU or the EMU). The country risk premiums are obviously country-specific ones, and they reveal the global intuitive perception of the major financial and capital market players about the economic and institutional development prospects of the individual countries. The presented strong institutional heterogeneity within the EU and the EMU shed some light on the enduring European crisis, nevertheless these findings are rather preliminary, and should be tested by more subtle indicators and on longer time periods as well.

## 5. Acknowledgements

For comments on earlier version of this paper, I thank two anonymous referees for helpful suggestions. I also thank for the comments my research fellows at the Institute for Political Science (CSC HAS, Budapest), my colleagues at International Business School (IBS, Budapest, Growth and Institutions research group) as well as my professors and colleagues at the Doctoral School in Economics at the University of Debrecen.

**Abstract:** *For Romania, European Integration came with new challenges for the entire society, especially for investment project promoters, including public higher education institutions. Investments in human capital development and education have an important role in a country's economic development and growth but, in spite of the large number of human resources development public projects being financed, major problems were identified in their implementation process, particularly factors from the macro-economic and institutional environment. Most of the current interest in this area is centered on identifying and analyzing these key factors since their understanding might lead to ensuring an improvement of the implementation process and to a project's success. In this context, our paper's objective is to provide a set of critical success factors for HRD projects' implementation process by developing a framework for external environment factors' analysis from a public project management perspective. Taking into consideration the current impact of the external environment' factors upon projects in Romania, in this paper we chose to focus our attention only on the critical success factors of the external socio-economic, institutional, technological and cultural environment, that affect the implementation phase of a project. We started with an analysis of the Romanian context that allowed us to develop a conceptual framework. We then realized a survey on a sample of three Romanian public universities which implemented projects in human capital development by developing and applying a questionnaire to 112 persons involved as management in projects in order to identify the key factors from the external environment that affect a project's implementation process. Results show that the most significant factors, with a negative impact, are political and economical ones while technological and cultural factors are perceived as factors with a positive influence. Our conclusions have a high informational content and can be useful for those involved in policy making and building institutional capacity in terms of human resources development.*

**Keywords:** *project management, human resources development project, critical factor, PESTC analysis, implementation management.*

## 1. Introduction

Although Romanian universities, especially public ones, should access EU funds for HRD projects, the current low absorption degree and the problems manifested as well as the certainty that the funding will reappear in the next financial programming period (2014 – 2020), underlie the necessity as well as the opportunity to study HRD

projects' implementation framework and the factors that determine its success or failure.

In this sense, our study's objective is to provide a set of critical success factors for HRD projects' implementation process by developing a framework for external environment factors' analysis from a public project management perspective.

In order to fulfill the paper's objective, we have started with an extensive literature review, approaching the topics of project management, HRD projects, key factors and their study in the specific literature, followed by an analysis of the Romanian context which allowed us to develop and test a conceptual framework.

It should be noted that even though the originality of our research does not rely on the method applied (questionnaire survey) our results and conclusions have a high informational content and can be useful for those involved in policy making and building institutional capacity in terms of HRD.

## **2. Literature review**

### **2.1. Critical success factors in projects**

Project Management has seen in recent years an important growth as a research area given that the project work environment has become increasingly complex and unstable. In this context, the analysis of factors that determine the success or failure of the projects appeared, precisely because often project results do not meet stakeholders' expectations (Jugdev and Müller, 2005).

Key success factors in projects can be seen as a series of conditions, areas, circumstances that contribute to the fulfillment of projects' results (Ika, 2007) or, in other words, areas where "things must go right" (Rockart, 1978) for the successful implementation of the project and for its successful results.

Although the number of articles that analyzed projects' critical success factors is extensive (Kwak, 2002, Ika, 2007, Ika, 2012, Khang and Moe, 2008, Dvir et al, 1999, Stankovic et al, 2013), there is no general opinion regarding key factors: some factors seem to have a universal character, appearing in several studies, while others are linked to the specific nature of the project. Meanwhile, the increasing diversity of projects highlights some of their characteristics, depending on the type of project analyzed. The idea that projects are different and that these differences render differences in the "optimal" management path also appears in various studies (Howell et al, 2010).

Thus, for the hard category of projects (construction projects, institutional and technological infrastructure - equipment, software platforms), usually success is determined through quantitative criteria whilst for the soft category of projects (education, health projects), qualitative criteria are used (Crawford and Pollack, 2004, cited by Ika, 2007).

In terms of international development projects, the literature is relatively limited. Some of the most relevant studies are conducted by Khang and Moe (2008) and Ika et al. (2012), studies based on the analysis of responses obtained by distributing questionnaires. Meanwhile, Kwak (2002) performed a review of 10 categories of internal and external variables that act as challenges in international development projects. In the case of international development projects, the macro-economic and institutional environment's characteristics of the receiving country play an important role, along with internal factors related to monitoring and coordinating the project.

We consider that their importance is directly linked to the uniqueness of the macroeconomic, institutional and cultural environment of these projects, regardless of their field of activity (education, health and nutrition, water and sanitation sewage, environment, infrastructures, judicial or institutional reforms).

On the other hand, organizational development projects have been the subject of analysis from different perspectives, the most important being related to the information infrastructure (hardware and software) and integrated business systems connected to organizational change efforts and Business Process Reengineering. The critical factors in the implementation process occur mainly from the internal, organizational environment or from stakeholders' relationships as underlined by the studies of Chow and Cao, 2008; Stankovic et al, 2013; Ram et al., 2013.

Human resource development projects implemented through structural instruments have both an international dimension, determined by the source of financing funds, approaching thus the typology of other projects funded by international organizations (World Bank, EBRD) and an organizational development dimension which completes projects that aim the organizational infrastructure component.

Human capital development is one of the major directions through which a country can remodel. SOP Human Resources Development (SOPHRD) has a range of measures and funding lines, some of which are accessible to universities in general (in particular, to the public ones). Through structural instruments of European Union, public universities in Romania have been a major recipient of these funds through three priority axes: "Education and training in support for growth and development of knowledge based society", "Linking lifelong learning and labour market" and "Increasing adaptability of workers and enterprises". In addition to these axes and areas, universities could access, as training providers, funding from other priority axes, especially "Promoting social inclusion".

The current low absorption stage of this program, the gaps manifested in its progress, and the certainty that the program will reappear in the financial programming period of 2014 - 2020, requires studying the implementation framework and the factors that can determine its success or failure.

Although extremely generous in terms of investment and human capital development possibilities, SOP HRD showed major gaps in implementation. The national studies in this area aren't numerous, being limited to professional analysis of experts or consultants or policy analysts. Results may be mentioned that have indicated both economic and political system problems, both at a macro environment and organizational and institutional: the implementation structures, the human resources involved and the systems of monitoring and evaluation (Oprescu et. al., 2007, Gherghinescu & Rinderu, 2011), unknown calendar of the calls for projects, lagging deadlines for project submission, modifications in the documentation for the applications for financing, bureaucratic excess (bureaucratic fanatics), delayed evaluation of the applications (Cace et. al, 2009), lack of analysis regarding ways to complete the target group, unrealistic financial forecasting for the project, overestimated indicators (Braşoveanu et. al, 2011), or unstable political environment, which has undergone many changes in 2007-2012 (Stoina, 2012).

All of the mentioned aspects underline the necessity for studies to highlight critical implementing factors depending on the specifics of beneficiaries.

### 3. Research model and design

Taking into consideration the current impact of the external environment' factors upon projects in Romania, as underlined above, in this paper we chose to focus our attention only on the critical success factors of the external socio-economic, institutional, technological and cultural environment, that affect the implementation phase of a project.

The starting point of this research was the model proposed by Ika et al., 2012, which we adapted and developed by focusing on the external environment variables that may affect a HRD project. In view of our research objectives, we consider that the most appropriate external environment assessment model is PESTC which, as shown in the specific literature, is often used as a strategic instrument in project management (Belassi and Tukel, 1996). The model contains factors that can be divided into five categories: political, economic, social, technological and cultural. The variables chosen for each category are presented in table 1 below.

**Table 1: The framework model's variables**

Type of factor	Variables
Political	Stability of the projects implementation' legal framework; The complexity of the projects implementation' legal framework; The existence of support from local authorities or other public bodies in the implementing process; Faulty governmental management of European funding sources.
Economic	Self-financing capacity of projects at the government level; Self-financing capacity of projects at the institutional level; Labor market characteristics.
Social	Partners' experience in implementing EU funded projects; The demographic evolution of groups connected to the academic environment; Potential beneficiaries' reluctance to integrate in the target group.
Techno-logic	The partners' quality of the technological / research infrastructure and informational system; The partners' logistic capacity to support the project; Automation of operational procedures.
Cultural	Relations with the administrative system that manages EU projects; Stakeholders' attitude towards the possibility of project completion; Corruption in the institutions responsible of project implementation; Stakeholders' attitude towards change; The universities' perception within the economic and social environment and the community.

In order to better substantiate our model, we then analyzed each group or category of variable, as follows:

Political factors – currently the Romanian political environment is characterized by a high degree of instability, political tensions and a poor quality of regulations. Although experience has shown that one of the main issues in implementing HDR projects is its regulatory framework, the World Bank 2007 study placed Romania on the 71<sup>st</sup> place (out of 212 states) for its quality of regulations.

Economic factors - The economic environment should be characterized by growth, innovation and mobility, aspects that are a reflection of economic interconnections, the result of globalization, growing grazing due to technological advances. In Romania, we are faced with a general context of economic crisis that accelerates, underfunding and poor access to education with an uncertain nature of economic forecasts.

Social factors - such as demographic evolution, unemployment and the need for retraining, education level, unequal access to education by income, inclination towards continuing education such as lifelong learning, cross-border migration between rural and urban areas or from small towns to the cities, determine the need to implement projects aiming target groups of population in various stages of initial training or certain levels of professional development. On the other hand, the Romanian academic environment constantly tries, without a clear success, to integrate subject areas in initial and continuous training of human resources to meet the real needs of the market.

Technological factors are very important in the management of project implementation, logistics infrastructure, office equipment and hardware and software support, multimedia equipment and virtual educational platforms have grown more in the last decade within the Romanian public universities, for the following reasons: (i) the existence of alternative financing sources through projects and the increase the tax education, especially in socio-economic and legal sciences, and (ii) a broad financial autonomy that allows the use of resources according to the university's own institutional development strategy in accordance with the law.

Cultural factors are less studied in the literature as success factors of project implementation. We only found brief description of some in Kwak, 2002. However, their presentation is in terms of cultural differences that arise when projects involve partners from different countries (according to the comparative management study paradigm and not project management), when this paper proposes a different approach, that justifies their inclusion in the model (complement the traditional PEST model): taking into consideration national cultural factors that through their characteristics can support/impede the successful implementation of projects. On the other hand, we believe that there is a two-way relation between the institutional architecture of a country and its cultural paradigm: the cultural profile of a country consists of its institutions and the institutional framework is set up by the members of a country (culture) through their deepest values (Brancu, 2007).

On these grounds, we formulated our first research hypothesis, as follows:

H1. PESTC factors exert a significant impact on the successful implementation of HRD projects in Romania.

Corruption, institutional bureaucracy, unpredictable change and poor institutional governance are, in our opinion, the environment variables that define the institutional cultural context. Corruption is a variable that presents strong negative aspects in Romania. According to Transparency International, Romania registered a score of 48, whereas 0 means that a country is perceived as highly corrupt and 100 means it is perceived as very clean. Of the 176 countries surveyed, Romania ranked 66<sup>th</sup>, far from the rankings recorded by other EU countries. These variables are especially important for the issue of this paper since they may be generalized at an institutional level. In these circumstances, we consider that the political, economical, social and cultural variables indicated in table 1 above have a negative impact on HRD projects' implementation, while technological ones, especially

logistics and infrastructure contribute to the project's success, ensuring a proper functioning of the project partnerships, a real-time relationship with the target groups, the application of modern methods for conducting trainings and the possibility of implementing software platforms for practical applications (business simulation). Thus, we then formulated the 2<sup>nd</sup> research hypothesis:

H2. Political, economical, social and cultural factors have a negative impact whilst technological factors have a positive impact on HRD projects' implementation.

Political factors essentially determine the macro context in which any type of project develops, in that it generates the legal and regulatory framework of the entire project cycle, which includes the implementation phase. The relations between national responsible authorities and the European Commission are fundamental in ensuring the coherence of programs and projects. Given the political instability generated effects in the management of the Managing Authority, the European Commission's audit reports were largely negative, causing interruption and suspension of funding. The uncertain nature of economic forecasts generated a lack of confidence of both beneficiaries in terms of self-financing ability and target groups in terms of results' sustainability. As such, we formulated the third hypothesis:

H3. The negative impact of the political and economical factors is more significant than that of the social and cultural factors upon HRD project's implementation.

## **4. Methodology and results**

### **4.1. Research methodology**

Hypothesis testing and validation was performed using quantitative methods of gathering information, a questionnaire-based survey, considered appropriate in the context of the research's objective.

The questionnaire was developed with the intention to offer the possibility of appreciating the impact of preselected variables from the external environment, as perceived by the subjects. The questionnaire contains a set of 18 items, grouped according to the five types of factors from the external environment, as mentioned and explained in table 1 above and it also includes a section for the collection of socio-cultural information considered relevant for testing the established hypotheses. For each item a five step scale was attributed, from major negative impact (1) to major positive impact (5). The process of information collection was performed during two months (January and February 2013) by distributing questionnaires to a number of 210 employees of 3 public universities from the Western Region of Romania, representatives in terms of academic and research results, that developed such projects since 2007. The sample selection process involved personnel that was part of a HRD implementation process from a decision-making point of view (management functions) or from an administrative one (administrative functions).

### **4.2. Data analysis and interpretation**

The information collected was processed using SPSS 17. Of the 210 questionnaires distributed, 112 were validated. Our preliminary analysis of the data revealed that the sample is fairly balanced with regards to the socio-cultural variables considered. The descriptive analysis of the sample shows that the majority of the respondents are male, within the 30 – 45 age group and with a longevity under 5 years. Also, the respondents are predominantly teaching staff (64%) taking into account that the SOP HRD's structure encourages active participation of the teaching staff in project

management structures. As for the respondents' experience in implementing HRD projects, for both of the variables considered (project team function and participation in HRD projects), results show that our targeted group is highly experienced due to their decision-making positions in project teams and their participating in a large number of projects of this kind. Thus, we can state that all of the information provided and analyzed as follows is consistent and reliable from this point of view. In order to determine the integrity of the success factors' scale, we performed a reliability analysis by computing all of the variables for the five external factors.

**Table 2:** Reliability analysis of the critical factors

<b>External environment factors</b>	<b>Cronbach alpha coefficient value</b>
<b>Political factors</b>	0,837
<b>Economical factors</b>	0,712
<b>Social factors</b>	0,446
<b>Technological factors</b>	0,746
<b>Cultural factors</b>	0,754

The values calculated for the Cronbach alpha coefficient (as shown in table 2) achieve a level greater than 0.7, except for the Social factors. When analyzing individual items within the scale, we observed similar coefficient values, thus proceeding to the elimination of this factor from our research framework. This poor internal consistency of the Social factors can be explained through our selected sample characteristics – implementation project team members, when the individual items included in this factor category are perceived with a greater intensity by HRD projects' targeted group since they determine the project's social output.

Next, we focused on analyzing the respondents' perceptions regarding the type of impact (negative or positive) on the implementing process of the four external factors, through their attributed items (table 3).

In view of the project management staff's perceptions, the four remaining types of external environment factors have a significant impact on the implementation process, namely a negative one when analyzing political and economical ones and a positive effect in the case of technological and cultural factors, thus partially confirming H1.

**Table 3:** External environment factors' impact analysis (N=112)

<b>External environment factors</b>	<b>Negative impact</b>	<b>Positive impact</b>
<b>Political factors</b>	82,1%	<b>12,5%</b>
<b>Economical factors</b>	58,9%	<b>39,3%</b>
<b>Technological factors</b>	<b>7,1%</b>	87,5%
<b>Cultural factors</b>	<b>25%</b>	62%

A detailed analysis of the perceived items' impact showed that in the case of political factors, 58,9% of the respondents appreciated *The complexity of the projects implementation' legal framework* as a major negative impact item, followed by the *Stability of the projects implementation' legal framework* – 53,6% and *Faulty governmental management of European funding sources* – 51,8%, while *The existence of support from local authorities or other public bodies in the implementing*

process is perceived as a minor negative impact factor by the majority of the respondents – 30,4%

For the economical factors, *Self-financing capacity of projects at the government level* and *Labor market characteristics* are perceived as major negative impact factors (by 44,6% and 32,1% of the respondents) on project implementation while 39,3% consider that *Self-financing capacity of projects at the institutional level* has a major positive impact.

Technological factors, namely *The partners' logistic capacity to support the project* (51,8%) and *Automation of operational procedures* (50%) are perceived as factors with a major positive impact and *The partners' quality of the technological / research infrastructure and informational system* is also a positive impact factor as appreciated by 35,7% of the analyzed population.

As for the cultural factors, three items are categorized as generators of major positive impact (*Stakeholders' attitude towards the possibility of completion of the project* – 37,5%; *The universities' perception within the economic and social environment and the community* – 35,7% and *Relations with the administrative system that manages European projects* – 33,9%) and two as negative ones, *Corruption in the institutions responsible of project implementation* – 44,6% with a major impact and *Stakeholders' attitude towards change* – 23,2% as a minor impact. These results partially confirm H2 since Cultural factors are perceived by our studied group to have a positive impact on the HRD projects' implementation process and H3 could not be validated by virtue of the factors' obtained type of impact.

## 5. Conclusions and discussions

As stated in the beginning, our research aimed at identifying the main factors from the external environment that affect a HRD project's implementation success. Throughout the paper, we underlined the necessity and the relevance of PESTC analysis in terms of strategic project management and operational project management, focusing on project's implementation process due to the current problems encountered. The research's results highlighted that Political and Economical factors have a major negative impact on the project's implementation process, as perceived by the public universities' staff.

Contrary to our arguments, based on other specific studies and observations, Cultural factors, as perceived by our sample, are shown to be of a positive impact upon the implementation process, results that indicate an optimistic approach as consequence of past success in developing and implementing such projects.

An unexpected outcome of our study was the exclusion due to reliability scores of the Social factors from the designed research model, aspect explained via our investigated sample's characteristics.

In terms of implications, our research sheds light on critical factors in HRD public projects and contributes to the current specific literature since it shows that there is a significant impact, albeit often negative, of external environment's factors and project implementation which ultimately should lead to project success. Also, as a practical implication, our study identifies the main factors that should be improved by policy decision making bodies in order to ensure a positive evolution of a HRD project (table 4).

**Table 4:** External environment factors' impact ranking

Negative impact factors		Positive impact factors	
1	The complexity of the projects implementation' legal framework	1	The partners' logistic capacity to support the project
2	Self-financing capacity of projects al the governmental level	2	Stakeholders' attitude towards the possibility of completion of the project
3	Corruption in the institutions responsible of project implementation	3	The universities' perception within the economic and social environment and the community

The limitations of our research arise from the relatively modest sample investigated, which might generate a low capacity to generalize the results but also from not taking into account project success measures.

Thus, our study opened opportunities for further research, such as analyzing the correlation between the factors identified and specific project success measures for HRD projects, widening the population investigated by including HRD projects' targeted group and their perception of the factor's impact and even determining the factor's importance according to project lifecycle.

## 6. Acknowledgements

This work was possible with the financial support of the European program „Adaptation of the university curricula of master to the labor market in Romania in the projects financed from structural and cohesion funds,, Contract POSDRU/86/1.2./S/64076, developed by West University of Timisoara, Faculty of Economics and Business Administration.

## **SOCIAL CRISIS – AN IMPEDIMENT TO SUSTAINABLE DEVELOPMENT**

**Capmare Irina-Cosmina**

National Institute for Economic Research, Romanian Academy, Bucharest,  
Romania  
icapmare@gmail.com

**Abstract:** *This paper is about social crisis and sets to give a dimension for this non-effective current. The paper is addressed to all persons interested in this domain, especially for those that work in this sector (non-governmental sector, third sector) and that need to have a better perspective on the situation. The methodology was based on self documentation which involved a wide range of materials: reports, case studies, paper works, articles, specific sites, European Union guides. This paper underlines the bad influence of the social crisis on sustainable development. My research includes both quantitative and qualitative dates; the ideas are embraced by my own convictions on the topic and tend to express also my beliefs on the matter. The added value of the paper is provided by the elements brought together: the topic, which, as common as can be, has a critical importance for the economy, blended with new information related to European Union Funds abortion and statistic dates regarding the work market in our country. The paper starts with an introduction that offers general information about the topic, a short background on the next headlines. As follows, each headline surprises with punctual elements of social crisis: determinant causes, solutions found, institutions involved, conclusions. The results of the paper shows that institutions in Romania are concerned about this situation and fight to bring out the best solutions, even if community is not totally prepared to accept it. Besides Romanian institutions, we have the support of the European Commission, through the European Union Funds. The Commission brings also the know-how of the other European Union Countries that confronted with these situations and, in better conditions know, sets here good practices within the projects they finance. This paper should be read and acknowledged as a base for the social economy development and it aims to create an interest for more persons in contributing to the strategic growth of the country and people.*

**Keywords:** social crisis; social exclusion; sustainable development; European Union

**JEL classification:** Z13; J14; J61; F22

### **1. Introduction**

The first question we're asking is how we define social crisis and, why it is so important to the economic growth and sustainable development.

We already know that global economic downturn has had negative social outcomes for individuals, families, communities and societies, and its impact on social progress in areas such as education and health will only become fully evident over time.

Once with the 80's, Romania has resented an impoverishment process of the people, more accentuated in the transition period, by the two crisis: 1991-1993 and 1997-2000.

'The socio-economic evolutions registered in the last years have led to the poverty level of 18.8% in 2001, and the extreme poverty rate level up to 5.9% in 2004. The drastically reduction of the number of work places, the diminishing of the real level of salaries and the tax wedge in particular on the low paid have represented important causes of incomes 'depreciation. The increase of the life costs in the 1997-2000, has not been proportionally accompanied by an income increase, which implicitly lead to severe poverty'. (Impacts of the international economic crisis in Romania 2009-2010:14).

As the crisis deepened, more and more people have shared the belief that the economic crisis has drastically deteriorated the country economic situation and their household's living conditions. In August 2010, more than 92% of population considered that the economic crisis hit seriously the Romania's economy and 84% declared that their households were 'much' or 'very much' affected.

In the period of financial and economic crisis, households often adopt coping strategies, such as making changes in household expenditure patterns; however, these negatively influenced education, health and nutrition outcomes, which may lead to lifelong deficits for the children affected and thus perpetuate the intergenerational transmission of poverty. Given the fragility of the economic recovery and the uneven progress in major economies, social conditions are expected to recover only slowly. The increased levels of poverty, hunger and unemployment will continue to affect billions of people for years to come.

It is essential that Governments take into account the likely social implications of the economic policies. It has been shown, time and again, that economic policies considered in isolation from their social outcomes can have dire consequences for poverty, employment, nutrition, health and education, which, in turn, adversely affect long-term sustainable development. The gap between economic policies and their social consequences can create a vicious circle of slow growth and poor social progress. Universal social protection systems and active employment generation programs should become permanent measures, not temporary components of national crisis response measures. The recession has also affected various social and economic groups in very different ways. In general, women have been disproportionately adversely affected, but in some economies, the adverse impacts on men have been more severe than on women. In other economies, less skilled workers, youth, older persons and migrant workers have suffered in terms of lost jobs, benefits and earnings.

Social crisis exists over time and it became more accentuated in the economic downturns. Usually it is associated to poverty, but the new policies at European level raised the importance of social economy to a higher level. Now, we talk about a protective society where women, children and old persons are starting to be taking care through special programs. It started to come to our attention that things thought to be part of the Romanian society such as family violence, women exploitation at work, the low esteem of women in society, migration of workers to western Europe, children abandoned, low level qualifications, all these are social crisis features. If we want to overpass the economic crisis we have to be aware of our internal social difficulties and to solve them. Poverty will not disappear by its self and Romania will not lose the poverty etiquette until we give priority to our people.

Lately defined, sustainable development appears as an horizontal objective of the European Union strategy for society development. According to SOP HRD's (Sectorial Operational Program Human Resources Development) co-financed by

European Union, the general goal for the society's sustainable development is to have people better prepared to face the present and the future challenges and to act responsibly for the next generations.

For this end, the initiatives to be taken must develop learning in all the fundamental areas, learning to know, learning to leave together, learning to do, learning to be and learning to transform oneself and society.

## **2. Social Crisis Key Elements**

The social crisis term is complex by itself; it expresses the weaknesses of a society. 'In 2008 the EU was hit by the worst global recession for decades. The impact of this major crisis on economic growth and unemployment was felt almost immediately. But the social impact of the crisis, feeding through more indirect channels, is only beginning to appear'. (Social Europe, 2011:37).

The key elements are: migration, unemployment, social exclusion. Each element has its own particularities and from it, we can expand even more. Even if these elements exist in every country, they start to differ once by the effect on society, economy and second, by the quick reaction they are being solved by the Government. The relationship between social crisis and sustainable development is much tied since one influences the other. If a society cannot overpass its social crisis by solving its own problems, we cannot talk about growth, development, and a healthy, strong, well prepared new generation.

### **2.1 Migration**

Workforce migration has major consequences on families: it reduces marriage and natality rates, as well as divorce rate. Migration influences also the relation between sexes; women that work abroad starts to get used with a good income, become more independent financial and not only. This experience gives them more safety and discretion. These are good parts, so why consider migration a weak point for social development?

People leave to work abroad first and foremost for money (for 'better incomes'), irrespective gender, age, education, marital status and number of children.

The majority of all migrants working abroad were married when they left Romania for the first time. More than a half of the married migrants, women and men, left children (0-18 years) at home. Nonetheless, 28-30% of the married migrants (with or without children at home) remarried (legally or consensual union) abroad.

The economic crisis has added negative financial effects to the existent damaging effects upon the family environment. Almost one in every three households with migrants abroad has experienced a fall in remittances. Thus, 10% of all childless households, 5% of the households with children and parents/relatives at home and 32% of the households with children/parents working abroad declared in August 2010 that the money received from overseas have decreased due to the crisis.

All data indicate that emigration for work abroad will not decrease in the future. Nor will a large number of migrants return in Romania at least not for many years from now. For example, only one recruiting platform ([www. Tjobs.ro](http://www.Tjobs.ro)) reported that in 2010, there were 592,183 online applications and 138 thousands working contracts abroad were concluded.

In January 2011, more than 64 thousands persons searched for work abroad through the same platform Emigration for work abroad from Romania is circular, which means that migrants alternate periods of working abroad with periods at home. The

highest rates of leaving Romania for the first time were recorded in 2005. Since 2006 the share of people leaving for work for the first time has continuously declined. Most returned migrants left Romania during the economic crisis in 2008-2009 when the demand for new workers was strongly declined. Thus, the migrants returned due to the crisis are predominantly among the migrants who left Romania for the first time later than those who succeeded to stay abroad.

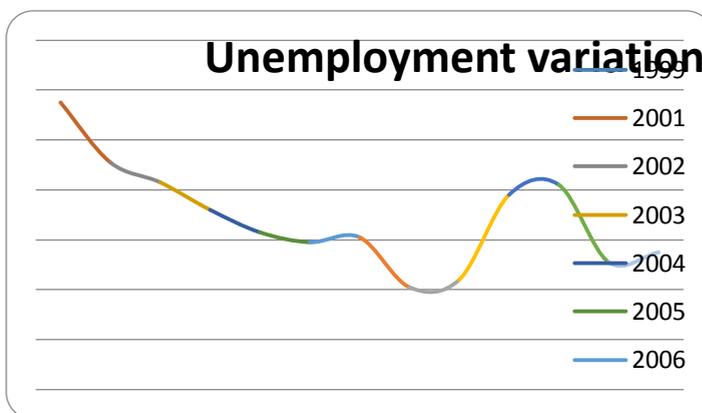

In multigenerational households, retired grandparents provide an important contribution to the household budget, particularly in the households of unemployed and of informal workers. On the other hand, grandparents are in charge with the domestic labour and the care for children.

Taking into consideration that a big part of migration consist in young women, we talk about the diminish of reproduction capacity which leads to a decrease of natality rage, Romania being classified one of the low rage natality country in Europe.

On the other hand the children left in the care of the relatives, of the grandparents, of the neighbors have originated a social problem regarding their care, supervising, frustration feelings or school abandon. If we take education as a national priority, then children raised by their grandparents don't live in a good situation in terms of authority, with less firm control, even if the affection and responsibility compensates a little. Still, a good education one that fits the requirements of a knowledge-based society and market economy is hard to reach when the new generation doesn't grow leded by new mentalities.

## 2.2 Unemployment

Unemployment is an element that becomes more visible once with a financial crisis. Unemployment is also the weak point that causes impoverishment. In our country starting with 2008, 2009 unemployment started to grow and rich the maximum level in 2010 with 8.2%. Nowadays, according to the statistics of the National Employment Agency, we see improvements, in 2012 the unemployment rate decreased to 5.5.

**Figure 1:** Unemployment variation  
Source: National Agency for Unemployment

Unemployment is different determined at rural and urban area. In urban area, finding a job can be easier due to the fact that persons are more bound to use technology, have better skills or education, similar experience, they are more open minded and

easier to access a location. In rural areas the interest in finding and also maintain a job is lower since persons prefer or choose to live from subsistence agriculture.

Here we face another resistance in the sustainable development, that of persons not wanting to grow, to contribute to the development of the society. For the development of skills, qualification and self-esteem we have the European Social Fund (ESF). ESF projects in Romania give people the jobs and skills they need to benefit from the modernization of the economy and the new job openings this brings.

They are also helping build a fairer society with training and job opportunities open to all citizens, including the most vulnerable. Nationwide, the ESF is supporting information campaigns to encourage people to take up vocational training opportunities and lifelong learning. And the ESF is helping public employment services to become more proactive and offer better services to job-seekers.

Quality management systems are being installed in municipalities and training in customer service techniques is being delivered. In rural areas, one-stop shops to deliver a range of public services more efficiently are helping job-seekers and citizens in more isolated communities.

The results of these actions are reflected in numbers. Romania is situated lately, among the countries that have the smallest unemployment rate. Unfortunately this is not enough to cover the other causes of the social crisis and poverty.

### **2.3 Social Exclusion**

The European Union published within its 2004 Joint report the following definition of social exclusion: 'Social exclusion is a process whereby certain individuals are pushed to the edge of society and prevented from participating fully by virtue of their poverty, or lack of basic competencies and lifelong learning opportunities, or as a result of discrimination. This distances them from job, income and education opportunities, as well as social and community networks and activities. They have little access to power and decision-making bodies and thus often feeling powerless and unable to take control over the decisions that affect their day today lives'.

Social exclusion is equal to disadvantaged persons through gender, religion, social layers, nationality, education, working skills and handicap. In order to reinforce social inclusion Romanians need to accept and embrace these differences, which unite us in the end, to militate for equality of chances and opportunities for all the persons.

The Government already took measures, by introducing laws that promotes hiring persons with disabilities. European Union through its funds encourages companies to hire women and gives importance to creating social enterprises, training and counseling for the disadvantaged persons, in order for them to find better and more suitable jobs. The violence in the family is a subject that remains unsolved yet, in terms that law exists, but without a good methodology in applying it.

European Union comes again with funds for projects that offer counseling to women involved in domestic violence, on how to solve this situation, for teenagers involved with drugs, in convicted to reintegrate in society and for other groups affected by the misconception or misjudgment, in order to eliminate the low esteem ideas and frustration. A person that doesn't trust its own abilities is incapable to overpass its statute of social excluded and forms a vicious circle that leads to a society denaturation. It is not enough for the inside or outside institutions to interfere in their development and support, if the entire nation doesn't change mentality, doesn't accept them, doesn't encourage them for the qualities they have, for what they have to offer. It is not only one example that reaches our knowledge when it comes to

disadvantages persons that proof to be more human, or more gifted than any other person that never confronted with social exclusion.

### **3. Old Generation vs. New Generation**

Old generation vs. new generation or generation x vs. generation y. Nowadays we confront with knowledge-based society, very difficult to be kept up by the old generation. Even so, what is the relation with the sustainable development and social crisis? As mentioned before, society splits in persons that have access and support to technology and advanced knowledge and persons that tries to keep up to this changes. If sustainable development means among other growth, development and to act responsible for the next generation, this means that in order to contribute to a better society we have to analyze deeper the gaps between generations.

Let's take the example of children that should have access to the some information and technology. Sill, because of migration of their parents, or the fact they live in rural areas, they don't have access to the same support and guidance. In this way, raised by grandparents or in schools that are not properly equipped, they reach college (for those that don't abandon school earlier) with a handicap of knowledge that is very hard to repair.

This gap leads to frustration and low self-esteem that aggravates even more the initial situation. In terms of finding a job, it is very likely for an inexperienced person to find a job quicker that an elder one with the advantage of new society requirements: handling IT&C (Information, Technology and Communication) equipment and foreign languages.

If it seems that generation X is a cause of social exclusion, let's take a look on the other side, the lake of specialist prepared to take care of the old persons. It is a custom lately to immigrate in Western Europe in order to work in this domain, for better incomes, without special diplomas, instead of paying attention to our elder persons that are in needed for these services. Likely for us, European Union finances projects for creating elderly homes and also for training persons in becoming elderly caregiver. There is still interested in this domain since the co-financed lines were closed a few after opening, because of the big number of projects submitted and budget exhaustion.

### **4. Solutions to Social Crisis – Actions and Results**

European Commission has decided to create a fund to help the most disadvantaged persons in European Union The fund will support the member states systems of providing food for the most disadvantaged persons and clothes and other goods for the homeless persons and material deprived children. There will be allocated 2.5 billion euros, for the period 2014-2020, at European level. In Romania, the program had encountered a few difficulties. In Bucharest, for example, only 30% of the persons received the 12 foodstuff, public authorities justifying the difficulties in supplying some of the foodstuff.

The city halls, through social protection departments, started to distribute starting 5<sup>th</sup> of November 2012 the welfare from intervention stocks, for the most disadvantaged persons in Romania, but the list of foods sometimes still lacking some products. It is also thought, that the lack of organization or the stiling of goods would be another reason for this community program not to work as planned.

One of the main characteristics of material deprivation is the incapacity to have access to adequate quantitative and qualitative food. The proportion of the EU

population who cannot afford a meal with meat, chicken, fish (or vegetarian equivalent) every second day – which is a base need according to Health World Organization – was 8.7% in 2010, meaning over 43 mil persons. The first numbers for 2011 shows a worst perspective.

If this was a solution to social crisis, another solution is given by the European Union funds through the ESF (European Social Funds). The European Union is committed to creating more and better jobs and a socially inclusive society. These goals are at the core of the Europe 2020 strategy for generating smart, sustainable and inclusive growth in the EU. The current economic crisis is making this an even more demanding challenge. The ESF is playing an important role in meeting Europe's goals, and in mitigating the consequences of the economic crisis – especially the rise in unemployment and poverty levels.

One financing line, 6.1 Social economy is addressed strictly to disadvantaged persons with the scope of social inclusion. For the projects submitted in 2009, the implementation started in 2010-2011, results started to be seen in 2012 through activities such as social enterprises created, training delivered for vulnerable persons. In terms of statistics is very hard to find real numbers, regarding these projects, even if it is in terms of number of projects or results. We only hear about the poor absorption of funds but less about results. In 2011 the 6.1 line opened again, this time it was known that the number of projects submitted in the first day overpassed 2000. The answer received is that all projects were cancelled. In 2013, the ESF program is announcing that the line may open again. It is a good practice but unfortunately in the same spirit of uncertainty. This would have been a good solution to social crisis waiting to find space in the local strategy.

## **5. Conclusions**

In conclusion, our actions influence next generation and the growth of our society. Therefore it is a must to embrace the new policies and think forward for actions more complex and more suitable to our needs. This means helping each other to eliminate social exclusion actions, all generations to mix together and learn from each other, creating jobs, and encouraging persons to be more opened to the new solutions there are provided.

The economic crisis has served as a reminder that it is essential for people to be healthy, educated, adequately housed and well fed to be more productive and better able to contribute to society. In other words, social policy in general, as well as measures to end poverty in all its dimensions, should be an integral part of macroeconomic policy to promote development. Approaches to poverty reduction should, therefore, be developmental and holistic, integrating economic and social policies to achieve people-centered development outcomes.

Risk of poverty or social exclusion rises to 46 percent in Romania, due to population decline to 19 million people, the highest in the entire European Union, in all age groups, results from a study presented by Bloc National Sindical (BNS).

The economic crisis led to job loss, but also to an increase of work overtime for fear of not losing job. Consequently, in many households, children are exposed either to risk-of-poverty associated with parents' job loss or to reduction of the quality time with parents.

According to the recruitment site Myjob, over 86 percent of Romanians would leave to work abroad if they had a chance. Besides the nearly 2 million Romanians who have already left the country, more than 400,000 Romanians applied from January

to June 2010 for a job abroad. Given the austerity measures implemented by the government this summer, the number of those fleeing the country will invariably reach new peaks this year.

Much of the media focus in recent years has been on 'the new poor'. While it is undoubtedly true that many people who previously believed themselves to be secure are now falling into poverty, many of those who have been worst hit come from distinct vulnerable groups – in particular, people already experiencing poverty before the crisis, young people, people who are educationally disadvantaged, migrants and ethnic minorities, older people, children and lone parents.

Alternatives to the present approach are possible, but need to build and fought for through new alliances. The immediate solutions for social crisis would be:

- A pro-active social impact assessment on the causes and consequences of the crisis;
- Alternative exit strategies, which reduce deficits more slowly and invest in recovery, boost demand and include a commitment to a social model which offers adequate protection and equality of opportunity;
- A comprehensive rethink of the development model which has predominated in recent decades, with a view to devising an alternative that will allow for the hope of building a better life for all.

Social crisis has to be the first point to be solved for the next years for the good health of the population, for the economic growth but mostly for the sustainable development.

# REGIONAL DEVELOPMENT AND INNOVATION IN ROMANIA. CHALLENGES AND PERSPECTIVES

**Chirilă Lavinia Florentina**

*Doctoral School of Social Sciences, Department of Economics, Faculty of Economics, University of Oradea, Oradea, Romania  
lavinia\_cipleu@yahoo.com*

**Abstract:** *Regional innovation is considered one of the most important drivers of development at present. Innovation is the tool that can help regions develop regardless of their natural resources and potential. The main purpose of the paper is to foster the innovation at regional level in Romania in order to determine and highlight the need of further measures to increase regional innovation and regional development of Romanian regions in the current context of getting out of the economic crises. Romania is subject of discrepancies not only at European level but at national level as well in terms of economic development and regional innovation. The research undertaken in the present paper is a qualitative research and follows the model proposed by the Group of Applied Economics in the study called Manual of regional competitiveness assessment, and in the study called Romania's reindustrialization: policy and strategy, study commissioned by the Ministry of Economy, Trade and Business, and uses regional indicators of the eight Romanian development regions in order to measure the Competitiveness Index based on three Indexes, namely Economic, Social and Innovation Index. The data used was collected from Romania's National Institute of Statistic, National Centre of Prognosis and from the Eurostat database. The general objective is to enhance the great role of regional level in innovation and to sensitize the policy makers about the need to introduce a regional level in order to enforce regional innovation, the main way of improving regional competitiveness and regional development. The main findings reveal that the Romanian regions that invested more in innovation have a positive evolution in terms of economic growth over time so it is for the best of a region to invest in innovation, an aspect that should be taken into consideration by policy makers and private sector when planning the investments within a region.*

**Keywords:** *Innovation index, Economic index, regional innovation, regional development, regional competitiveness.*

**JEL classification:** *P25, R11, R58.*

## 1. Introduction

Regional innovation is considered one of the most important drivers of development at present. Innovation is the mean through which regions can develop and become more competitive regardless of their natural resources and potential.

Innovation is the solution for some important global challenges as the climate change, the need to limit fossil fuel energy consumption and global economic crisis (Cooke et al., 2011). Even more, there are authors who consider innovation the engine of economic growth (Asheim and Gertler, 2005), who argue that in order to

create a proper socio-economic framework for innovation development regional level has been given great importance.

The concept of innovative regions has been increasingly associated with the so-called knowledge region, a concept specific to the 'New Economy', based on two approaches: the first one is that knowledge emphasizes business competitiveness and the second one considers region as a platform for interaction that encourages accumulation of knowledge (Asheim, B., Cooke, P., Martin, R., 2006; M., Perry, 2010).

In order to enhance the actual position of Romania in terms of regional innovation and economic development, we should bear in mind that at present, in terms of economic development and regional innovation, Romania is subject of regional discrepancies at both European and national level. For example, in terms of economic discrepancies, in 2007 the Bucharest-Ilfov region, the region that contains the capital city, registered a GDP/capita almost 4 times higher than North-East region, the poorest at the moment (according to Romanian National Institute of Statistics). However, after 2007, when Romania joined the European Union, started a process of catching-up but it was hindered by the global economic crisis felt in Romania at the end of 2008. How innovative are the Romanian regions? and How does this influence the regional economic development? are the main questions that the paper tries to answer.

## 2. Methodology

In order to reveal the link between innovation and economic development of the Romanian regions have been investigated the Innovation Index and the Economic Index of Romanian regions in comparison in 2007 and 2011 and their evolution in the period.

The methodology used was proposed by the Group of Applied Economics in the study called Manual of regional competitiveness assessment (2007), and the study Romania's reindustrialization: policy and strategy (2010), study commissioned by the Ministry of Economy, Trade and Business, that uses regional indicators of the eight Romanian development regions such as: growth rate, GDP, net income per capita, percentage of research and development expenditure in total GDP, number of employees in the high technology sector and so on.

The qualitative research undertaken uses data collected from The National Institute of Statistic of Romania, The National Centre of Prognosis and from the Eurostat database.

The model of evaluation selects a set of indicators for the two directions, which it aggregates, by calculating a weighted average, as we can see in Table 1 and Table 2.

### 2.1. Indicators used for the identification of the Economic Index at regional level

**Table 1: The Economic Index**

Index		Weight
Economic Index (E)		

	E <sub>1</sub> GDP/capita	10%
	E <sub>2</sub> GDP growth rate	10%
	E <sub>3</sub> Labor productivity	30%
	E <sub>4</sub> Net exports	10%
	E <sub>5</sub> Gross fixed capital formation (% of GDP)	20%
	E <sub>6</sub> Net income per capita	20%
<b>Economic Index = 10%* E1+10%* E2+30% E3+10%* E4+20%* E5 +20%* E6</b>		

Source: GEA (2007) - Manual of regional competitiveness assessment, [on-line], [http://www.gea.org.ro/documente/ro/proiecte/manual\\_2007.pdf](http://www.gea.org.ro/documente/ro/proiecte/manual_2007.pdf), accessed on 21.08.2011, p.37;

The aggregate Economic Index weights of each component (according to Table 1) are: GDP per capita - 10%, GDP growth rate - 10%, net exports - 10%, labor productivity - 30%, gross fixed capital formation (% of GDP) - 20%, respectively net income per capita - 20%. Gross fixed capital formation (% of GDP) is not available in national statistics development at regional level; therefore, this lack will be taken into account in the calculation of aggregate economic index.

**Table 2: The Innovation Index**

Index		Weight
<b>Innovation Index (I<sub>i</sub>)</b>		
	I <sub>1</sub> R&D Expenditure (% of GDP)	40%
	I <sub>2</sub> Employment in high technology sectors	30%
	I <sub>3</sub> Tertiary education specializing in advanced research	30%
<b>Innovation Index = 40%* I<sub>1</sub>+30%* I<sub>2</sub>+30%* I<sub>3</sub></b>		

Source: GEA (2007) - Manual of regional competitiveness assessment, [on-line], [http://www.gea.org.ro/documente/ro/proiecte/manual\\_2007.pdf](http://www.gea.org.ro/documente/ro/proiecte/manual_2007.pdf), accessed on 21.08.2011, p.37;

The distribution of the weights between Innovation Index's components are: R & D Expenditure (% of GDP), accounts for 40%, and Employment in High Technology Sectors as well as Tertiary education specializing in advanced research, that have a weight equal to 30% each, with the observation that for this indicator could be found all sizes.

### 3. The regional economic development of Romania

Like other Eastern European countries, Romania has experienced in the last 20 years a process of deindustrialization. At national level, according to the data revealed by the National Institute of Statistics, there are relatively low inter-regional disparities compared to the other EU countries. Even so, we notice deepening trends of disparities in terms of GDP/capita between the region containing the capital city and the other regions, the centre-periphery model of development being felt in Romania as well.

There is a general trend of increasing regional disparities regarding employment, industrial production, investments and income between West-and East and from centre to periphery.

**Table 3: Regional Economic Index in 2007, compared to 2011**

Region	2007	Rank 2007	2011	Rank 2011	Change in Index score 2007-2011
North - East	0.697959	8	0.708029794	7	1,01 %
South - East	0.813539	6	0.845112988	5	3,16 %
South	0.859075	5	0.845318965	4	-1,38 %
South West	0.737657	7	0.698468193	8	-3,92 %
West	0.899428	3	0.880285436	3	-1,91 %
North - West	0.884216	4	0.830732309	6	-5,35 %
Centre	0.963781	2	0.899453286	2	-6,43 %
Bucharest - Ilfov	2.169459	1	2.319737587	1	15,03 %

Source: author's calculation, using Eurostat database

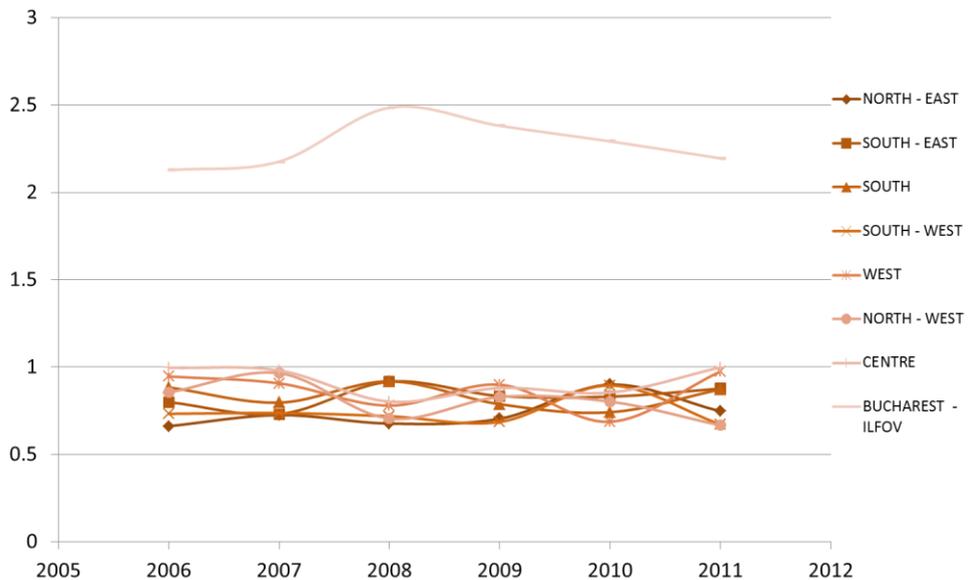

Figure 1: Evolution of Economic Index from 2006-2011

Source: author's calculation, using The Romanian National Commission of Forecasting database.

As Table 3 and Figure 1 reveal, Romanian regions were affected by the crisis and most of them registered a decrease in terms of economic development in 2011 towards 2007.

There were only three regions that managed to increase their economic indicators, namely Bucharest – Ilfov, South-East and North-East. The worst affected regions by the economic crisis were Centre region, followed by North-West and South West. The highest level registered by the Economic Index was registered in Bucharest-Ilfov region in 2008, but after 2008 the general trend is of decrease.

The highest levels of Economic Index are registered in the region containing the capital city (Bucharest - Ilfov) and in the regions situated in the West and Centre of the country, revealing a West-East and centre-periphery pattern of economic development. We notice a general trend of reducing discrepancies between West and East, because while the Economic Index of the regions situated in the Eastern part of Romania increased, the Economic Index of the regions situated in the Western part of Romania decreased, meaning we are facing a convergence tendency regarding Economic Index between Romanian regions except from Bucharest-Ilfov region, that keeps its growing tendency.

#### 4. Regional innovation in Romania

According to the Innovation Union Scoreboard for 2011 (IUS), Romania is one of the modest innovators with a below average performance. However, Romania recorded an average growth of innovation of 5% (IUS, 2011), being one of the catching-up leaders, but the process is slowing down.

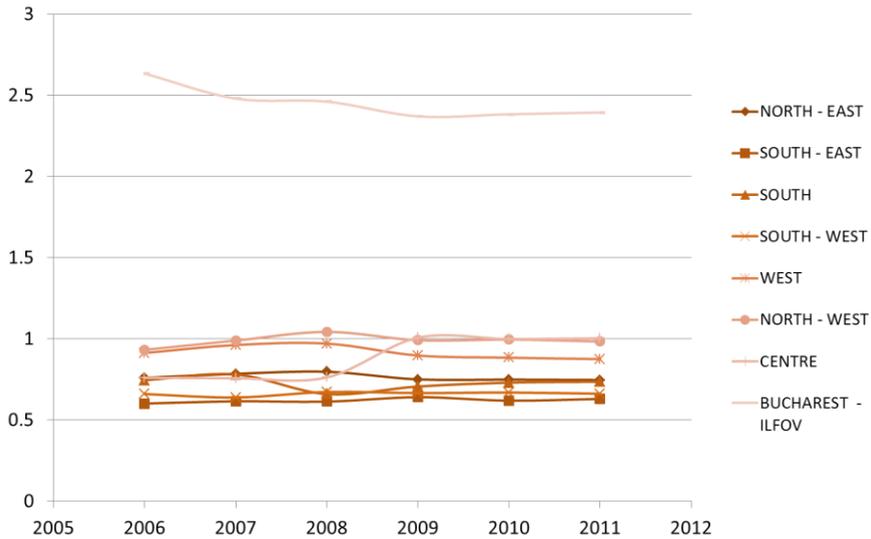

Even though according to data revealed by the National Institute of Statistics (NIS), from 2002 to 2008 the share of innovative enterprises raised constantly in the number of total enterprises, from 17% to 33%, our percentage is still very modest compared to other European countries.

Romania has serious problems in attractiveness of research systems, aspect revealed by several indicators: negative share of Non-EU doctorate students, firms do not invest in R&D, there are no innovative SMEs collaborating to others, we do not have PCT patents applications, etc.

Table 4: Regional Innovation Index in 2007 compared to 2011

Region	2007	Rank 2007	2011	Rank 2011	Change in Index score 2007-2011
North - East	0.688987369	5	0.639773243	6	-4.92%
South - East	0.508377613	8	0.510113379	8	0.17%
South	0.731411115	4	0.622063492	7	-10.93%
South West	0.543336237	7	0.685192744	5	14.19%
West	1.227587108	2	1.041428571	2	-18.62%
North West	0.920017422	3	0.948185941	4	2.82%
Centre	0.683930749	6	0.959863946	3	27.59%
Bucharest - Ilfov	2.721620209	1	2.640498866	1	-8.11%

Source: author's calculation, using Eurostat database.

**Figure 2:** Evolution of Innovation Index from 2006-2011

Source: author's calculation, using Eurostat database.

As we notice from Table 4 and Figure 2, the most developed and innovative region of Romania is Bucharest-Ilfov, mainly because there is a tendency of entrepreneurs to locate in the economic, social and politic centre of the country. On the second place in terms of innovation is situated the West region, placed at the western border of the country, its attractiveness being explained on the fact that it has a more easy access to foreign technology.

The Centre region registered an increase of investment in R&D from 2007 to 2011 and managed to surpass North West and South West regions.

The general trend reveals that the most innovative regions of Romania are situated in the western part of the country and the least innovative in the eastern part. There is also noticed a tendency to reduce the discrepancies between West and East, as the Innovation Index decreased in the central and western regions while the Innovation Index of southern and eastern regions increased.

## 5. Comparative analysis of Economic and Innovation Index in 2007 and 2011

Table 5: Comparative analysis of Economic and Innovation Index in 2007 and 2011 (1)

Region	Rank in 2007		Rank in 2011	
	Innovation Index	Economic Index	Innovation Index	Economic Index
North - East	5	8	6	7
South - East	8	6	8	5
South	4	5	7	4
South - West	7	7	5	8

West	2	3	2	3
North - West	3	4	4	6
Centre	6	2	3	2
Bucharest - Ilfov	1	1	1	1

Source: author's calculation based on Table 3 and Table 4.

Table 6: Comparative analysis of Economic and Innovation Index in 2007 and 2011 (2)

Region	Evolution of Rank in 2011 comparing with Rank in 2007	
	Innovation Index	Economic Index
North - East	-	+
South - East	0	+
South	- - -	+
South - West	+ +	-
West	0	0
North - West	-	- -
Centre	+ + +	0
Bucharest - Ilfov	0	0

Source: author's calculation based on Table 5.

In order to better observe the impact of innovation on economic development were created comparative Tables, Table 5 and Table 6, that show the evolution of the regions in terms of economic and innovation Index from 2007 to 2011.

The most spectacular evolution was registered by Center region (3 pluses in Innovation rank, 0 in Economic rank) and South region (3 minuses in Innovation rank, plus 1 in Economic rank).

An accelerated increase/decrease of indexes were registered by South-West region (2 pluses in Innovation rank, 1 minus in Economic rank) and North-West region (1 minus in Innovation rank, 2 minuses in Economic rank).

A moderate increase/decrease registered North-East region (1 minus in Innovation rank, 1 plus in Economic rank) while a constant situation registered Bucharest-Ilfov and West region (0 both in Innovation and Economic rank) and South-East region (0 in Innovation rank and 1 plus in Economic rank).

The main findings reveal that the first region in terms of innovation and economic development in 2007 and 2011 is Bucharest-Ilfov region, the region containing the capital city of Romania, that confirms the general trend existing in EU regarding innovation and economic development in capital regions and the regions situated in the Western and in Centre parts of Romania tend to invest more in innovation and tend to be wealthier than those situated in the eastern part or at the periphery of the country, that confirms again the general trend existing in EU regarding central-peripheral type of regional structure and the acceleration of the innovation and economic development direction from West to East.

## **6. Conclusions and proposals**

The regional level plays an important role in evolution of a nation's innovation and economic development and therefore it is important for Romania to increase its investment in innovation with a focus on regions.

The Romanian regions that invested more in innovation had a positive evolution in terms of economic growth over time, aspect that should encourage decision and policy makers to stimulate innovation at regional level.

There has been identified a pattern of investing in innovation from West to East and from centre to periphery, the same pattern being identified for economic development. Bucharest-Ifov is the first region in terms of economic development and innovativeness and it is followed by a contingent of other seven relatively homogeneous regions between which the differences are not very high.

The effort of increasing innovation should be coordinated at regional level, each region being specialized in a certain field, working in partnership with universities and research centers in the area.

We consider that the private sector should invest more in innovation in order to increase its economic performance, a phenomenon that would determine the increase of the regional economic development as well. The long-term effect of investing in R&D, in creating jobs in high technology sectors and also supporting tertiary education for specialisation in advanced research brings economic development and regional welfare, a welfare that spreads from the firm to the employees whose wages increase, to the local economy and finally to the regional level. It is the case of South and North-East regions, that through investing in innovation and having a good position in 2007 in Innovation Rank, managed to gain a better position in terms of Economic Index in 2011.

The great challenge for decision makers at regional level is to be able to offer facilities for entrepreneurs to encourage them invest in R&D and create workplaces in the sector. In addition to creating industrial parks and knowledge centres the decision makers should focus on communication and partnership at regional level between universities, private actors, interest and lobby groups and civil society, partnership that must be based on trust and lead to information and knowledge exchange that could increase the economic results for both private and public actors and for the region as a whole.

## **7. Acknowledgements**

The paper presents research results afferent to the doctoral research project "Using the specific instruments of regional policy of the European Union for growing economic competitiveness of Romanian development regions", conducted under the coordination of Professor PhD Mihai Berinde, within the Doctoral School of Social Sciences, Economics Domain, University of Oradea, partially supported by the strategic grant POSDRU/CPP107/DMI1.5/S/80272, title of the project "Performant PhD programs for forming competitive researchers in the European Area of Research" co-financed by the European Social Fund-Investing in People, within the Sectorial Operational Programme Human Resources Development 2007-2013.

# COMPARATIVE ANALYSIS OF RURAL DEVELOPMENT POLICY 2007-2013 IN ESTONIA, LATVIA AND LITHUANIA

**Dinu Mihai**

*Bucharest University of Economic Studies, Bucharest, Romania*

[mihai.dinu@gmail.com](mailto:mihai.dinu@gmail.com)

**Abstract:** *In this article will be carried out an analysis of the manner in which the three Baltic countries were able to implement rural development Policy at EU level. For rural development policy at EU level through EAFDR was allocated a budget of 96,3 billion € for the period 2007-2013. The total amount of funds for the three countries compared in this article is 3,54 billion €. The article begins with a comparative study on some characteristics of the national economy and the agricultural sector, such as population, GDP, GDP per capita, the total area, the area used for agriculture, the number of farms, number of persons engaged in agriculture, the importance of agriculture to the economies of those countries, will continue with the presentation of the amount of funds allocated for each axis and measure in the rural development programmes for the period 2007-2013 and another chapter will refer to the degree of access of funds from the EAFRD and shall end with a number of conclusions concerning the capacity of States to access EU funds. The three countries have experience in implementing EU funds considering that benefited from rural Development Plans in 2004-2006 and SAPARD. The main objective of this paper is to identify the amount and degree of accessing funds from EU rural development in Estonia, Latvia and Lithuania in the year 2012. The Estonian Rural Development Plan 2007–2013, Rural Development Programme for Latvia 2007–2013 and Rural Development Programme for Lithuania 2007 – 2013 cover the entire territory of these three states which is under convergence region. The data sources used in this article are from official statistical institutions such as Eurostat (European Commission), Central Statistical Bureau of Latvia, The Lithuanian Department of Statistics, Official Statistics Portal and Statistics Estonia.*

**Keywords:** agriculture, axes, EAFDR, measure, rural development

*JEL classification: Q18, R11, R58*

## 1. Introduction

The Republic of Estonia, the Republic of Latvia and the Republic of Lithuania are part of the Baltic States located on the eastern shores of the Baltic Sea and are members of the European Union since 2004.

The three countries have experience in implementing EU funds considering that benefited from the following programs in 2004-2006:

- in Estonia were prepared and implemented two strategic programming documents: the Estonian Rural Development Plan 2004-2006 (ERDP 2004 - 2006) financed from the European Agricultural Guidance and Guarantee Fund (EAGGF), Guarantee Section and the Estonian National Development Plan 2004-2006 (ENDP 2004 -2006) financed from the Financial Instrument

for Fisheries Guidance (FIG), the EAGGF Guidance Section, and the European Regional Development Fund (the ERDF) (technical assistance for the development plan) ;

- in Latvia have been implemented two programs: Single Programming Document and Rural Development Plan 2004–2006;
- in Lithuania were implemented 3 different programmes, Single Programming Document (SPD), Rural Development Plan (RDP) and Special Rural Support Programme (SRSP) which is funded nationally.

The Estonian Rural Development Plan 2007–2013, Rural Development Programme for Latvia 2007–2013 and Rural Development Programme for Lithuania 2007 – 2013 cover the period from 1 January 2007 to the end of 2013 and have been prepared following the provisions of the Council Regulation EC No 1698/2005 on support for rural development by the European Agricultural Fund for Rural Development (EAFRD). These programs cover the whole geographical territory of Estonia, Latvia, Republic of Lithuania and the entire territory of these three states is regarded as a convergence region, which means that in all administrative units of the NUTS second level, the GDP is below 75% of the EU average.

## **2. Data used for the analysis**

For achieving this article have been used data from the official statistical institutions such as Eurostat (European Commission), Central Statistical Bureau of Latvia, The Lithuanian Department of Statistics, Official Statistics Portal, Statistics Estonia. There were used information from national development programs of the three states and Rural Development in the European Union - Statistical and economic information - 2012. These data have been analyzed, processed and interpreted in order to observe the importance of the agriculture and rural development in a comparative approach between Estonia, Latvia, Lithuania and the European Union, the funds allocated to these countries and level of accessing funds from the EAFRD to the year 2012.

## **3. Information about the economy and agriculture of Estonia, Latvia and Lithuania**

The total area of Estonia is 45.227 km<sup>2</sup>, including 43.200 km<sup>2</sup> of land area. More than a half of the land area is forest land, one third is agricultural land, and one fifth is covered by mires and bogs. Estonia is one of the smallest countries in Europe, both by area and by population. Of the EU-27 countries, only Cyprus, Malta and Luxembourg have smaller size of population. Belgium, Luxembourg, the Netherlands, Denmark Cyprus, Malta and Slovenia have smaller territory than Estonia.(Estonian Rural Development Plan 2007–2013, Ministry of Agriculture, 2008)

The total surface area of Lithuania is 65.3 thousand sq. km. Lithuanian population is 3 million in 2012.

Latvia occupies a territory of 64 589 km<sup>2</sup>, of which the inland waters take up 2543 km<sup>2</sup> and dry land 62 046 km<sup>2</sup>, including agricultural land 24 710 km<sup>2</sup>, forest 29 503 km<sup>2</sup>; the total protected area is 10 523 km<sup>2</sup>.(Rural Development Programme for Latvia 2007–2013, Ministry of Agriculture, 2011)

In the following will be performed a short comparison of economy and agriculture of the three states based on various criteria and indicators such as population, GDP,

GDP per capita, the total area, area used in agriculture, the number of farms the number of people working in agriculture.

**Table 1.** Data relating to the economy and agriculture of Estonia, Latvia and Lithuania

Country	Estonia	Latvia	Lithuania	EU (27 countries)
<b>Criteria</b>				
GDP – Current Prices (Millions of euro) (2012)	16.998,2	22.258	32.781,8	12.899.149,5
Population (2012)	1.339.662	2.041.763	3.007.758	503.663.601
Gross domestic product (GDP) at current market prices (Euro per inhabitant) (2012)	12.688,42	10.901,36	10.899,08	25.610,64
Agricultural Labour Input Statistics: absolute figures (1 000 annual work units) (2012)	24,6	80,1	141,5	10.134,7
Share of Agricultural Labour Input in total population	1,84%	3,92%	4,70%	2,01%
The total area (km <sup>2</sup> ) (2010)	45.227	64.589	65.300	-
Utilised agricultural area in farms (km <sup>2</sup> ) (2010)	9.409,3	17.962,9	27.425,6	-
Share of utilized agricultural area in total area farms	20,80%	27,81%	42,00%	-
Total number of holdings (2010)	19.610	83.390	199.910	-

Source: Author processing data from Eurostat, European Commission

Lithuania is the largest country in the group of the three Baltic countries with an area of 65.300 km<sup>2</sup>. With an similar area is Latvia and Estonia is the country with the smallest area (45.227 km<sup>2</sup>). Regarding agricultural area where Estonia has the smallest percentage of area used in agriculture (20.8% in total) with a total area of 9409 km<sup>2</sup>, in Latvia are used for agriculture 179.620 hectares and area used for agriculture in Lithuania is 27.425 km<sup>2</sup> representing 42% of all area.

After analyzing data from the Eurostat, it can be seen that the country's GDP registered the highest value is Lithuania (32.781,8 millions of euro). Lithuania has also the highest number of population. However, the highest value of the GDP per inhabitant it can be observed for Estonia (12.688 euro / person). In all 3 person a notice in Estonia (12,688 euros / person). In all three neighboring countries value of the indicator is approximately equal to or less than half the average of the EU countries where this indicator takes the value of 25.610 euro in 2012.

Regarding the number of people working in agriculture in Lithuania is recorded the highest number of people working in the sector (141.500 people representing 4.7% of the total population of the country). Reported at EU level, all persons engaged in agriculture in the three countries is only 246.200 which represents 2.4% of total persons employed in agriculture in the EU.

Fewest farms are observed in Estonia (19.610), in Latvia are 83.390 holdings and Lithuania has the most holdings (199.910).

#### **4. The amount of funds allocated for 2007-2013 from the EAFRD for Estonia, Latvia and Lithuania**

For rural development policy at EU level, through EAFDR was allocated a budget of 96.3 billion euro for the period 2007-2013. The total amount of funds for the three countries compared in this article is 3.543.905.000 euro, allocated as follows:

Estonia have funds amounting to 723.737.000 euro, Latvia (1.054.374.000 €) and Lithuania received 1.765.794.000 euro.

The diversified level of agricultural development and directions of evolution of rural areas in the individual EU countries results in complex and diversified problems for the agricultural policy. That was a basic reason of giving a relatively great freedom to the individual member states to choose measures within the individual axes of the Rural Development Programmes. The allocation of expenses to the individual measures Member States should ensure that synergies among the economic, environmental and social aspects and, by assumption, it is supposed to reflect the priorities of rural development. The analysis of the allocation of expenses within the national rural development programmes will indicate similarities and differences of the use of the CAP support in the regional aspect. (Sadowski, A., Czubak, W., 2013)

**Table 2.** The amount of funds allocated for 2007-2013 through EAFRD for Estonia, Latvia and Lithuania

Source: Author processing data from Rural Development in the European Union - Statistical and economic information – 2012, European Commission

\* The axes and measures are as follows:

Axis 1: Improving the competitiveness of the agricultural and forestry sector: 111 - Vocational training and information actions, 112-Setting up of young farmers, 113 - Early retirement, 114 - Use of advisory services, 121 - Modernisation of agricultural holdings, 122 - Improvement of the economic value of forests, 123 - Adding value to agricultural and forestry products, 124 - Cooperation for development of new products, processes and technologies in the agriculture and food sector and the forestry sector, 125 - Infrastructure related to the development and adaptation of agriculture and forestry, 131 - Meeting standards based on Community legislation, 132 - Participation of farmers in food quality schemes, 131 - Semi-subsistence farming, 142 - Producer groups;

Axis 2: Improving the environment and the countryside: 212 - Payments to farmers in areas with handicaps, other than mountain areas, 213 - Natura 2000 payments and payments linked to Directive 2000/60/EC (WFD), 214 - Agri-environment payments, 215 - Animal welfare payments, 216 - Non-productive investments, 221 - First afforestation of agricultural land, 223 - First afforestation of non-agricultural land, 224 - Natura 2000 payments, 225 - Forest-environment payments, 226 - Restoring forestry potential and introducing prevention actions, 227 - Non-productive investments;

Axis 3: Quality of life in rural areas and diversification of the rural economy: 311- Diversification into non-agricultural activities, 312 - Business creation and development, 313 - Encouragement of tourism activities, 321 - Basic services for the economy and rural population, 322- Village renewal and development, 323- Conservation and upgrading of the rural heritage;

Axis 4: Implementation of the Leader approach: 411 - Implementing local development strategies. Competitiveness, 413 - Implementing local development strategies. Quality of life/diversification, 421 - Implementing cooperation projects, 431 - Running the local action group, acquiring skills and animating the territory as referred to in Article 59.

According to data from Rural Development in the European Union-Statistical and economic information-2012 of the three countries noted the following:

In Estonia were allocated funds amounting to 723.73 million euro divided into axes as follows: for Axis 1, Improving the Competitiveness of the agricultural and forestry sector and Axis 2, Improving the environment and the countryside, percentages are approximately equal, respectively of 36.48% for Axis 1 and 36,97% for Axis 2, with the amount of 264.034.000€ and 267.568.000€. Under Axis 1, for Measure 121 Modernisation of agricultural holdings were awarded more than half of the value of the funds, the amount of 147.038.000€. Within axis 2 dominates Measure 214, Agri-environment payments with funds worth over 168 million euro. For Axis 3 the amounts available are 94.941.000€. Within this axis were able to access funds for 2 Measures, namely 312 - Business creation and development having allocated the sum of 53.514.000€ representing 56,37% of the total axis and Measure 322 - Village renewal and development with funds amounting to 41.428.000€. For axis 4, Implementation of the Leader approach the funds allocated have the value of 68.607.000€, representing 9,48% of the total amount allocated to Estonia.

The amount of funds allocated to Latvia is 1.054.374.000€, 45% more than in the case of Estonia. Most of the funds are allocated to axis 2 (410.729.000 €, representing 38,95% of the total funds), followed by axis 1 with sums amounting to 396.245.00€ (37,58%). The largest sums for Axis 2 shall be allocated to the measure 212, Payments to farmers in areas with handicaps, other than mountain areas (185.770 € representing 45,23% of total axis 2). Under axis 3, from the total of 177.620.000 €, the sum of 97.551.000 € that is 54,92% shall be allocated to the measure 312, Business creation and development.

From the EAFRD most funds were allocated to Lithuania, respectively the amount of 1.765.794.000 €. We can say that the value is 2,44 times higher in comparison with Estonia, and with 67% higher than the funds allocated to Latvia. In the case of Lithuania, for Axis 1 is allocated the most funds, respectively, 42,51%, meaning the amount of 750.686 million of euro, followed by Axis 2 with a variable of 36,36% and an allocation of 642.014.000 € and Axis 3 with a percentage of 11,19% which is 197.508.000 €.

According processed and analyzed data we can see some similarities in terms of allocation:

- under axis 1, Improving the competitiveness of the agricultural and forestry sector, all three States allocate most funds for measure 121, Modernisation of agricultural holdings, which denotes the importance of modernising the pursuit of agricultural holdings through a better use of human resources and factors of production;
- within axis 2, Improving the environment and the countryside, in all three countries analysed so far predominate 214 - Agri-environment payments, with the largest amount of funds allocated to this measure in the total Axis 2, respectively the amount of 168.710.000 € in Estonia (which represents 23,3% of the total value funds intended for Estonia), 180.055.000 € in Latvia and 277.035.000 € in Lithuania.
- within the framework of the axis 3, Quality of life in rural areas and diversification of the rural economy, in all three countries, the largest part of the funds earmarked for this axis were directed to measure 312, Business creation and development, which means that those countries considered priority the overall objective of the measure aimed at the sustainable development of rural economy by encouraging non-farm activities in order to increase the number of jobs and additional incomes. The highest percentage of appropriations on this measure in this axis can be found in Estonia (56,37%) with the amount of 53.514.000 €, while in Latvia have the highest value of funds on this measure (97.551.000 €), but that represents 54,92% of the total axis 3.
- within the framework of the axis 4, Lithuania registred a total of 107.588.000 € which means 6,09% of total funds allocated, while Estonia benefits from 68.607.000 € that represent 9,48% of the funds allocated for this country and Latvia is ranked the last place having only 28.136.000 € representing 2,67% of the total.
- for axis 5 Technical assistance, 511, all three countries have similar percentages for the support of this axis, respectively a percentage of 3,85% to 3,95% and amounts to € 28.586.000 in Estonia, 41.645.000 € in Latvia and 67.997.000 € in Lithuania.

## 5. The degree of accessing funds in Estonia, Latvia and Lithuania until September 2012.

With the EU funding support it is expected to increase the competitiveness of the rural areas creating attractive living and working environment by introducing a complex problem solving for land owners involving land fragmentation, reduction of irrational local road network, lack of infrastructural facilities, and etc. (Pasakarnis, Giedrius, Maliene, Vida, 2011, pg. 1424).

Regarding the degree of access of funds are listed below sums granted until September 2012 under the EAFRD for analyzed countries.

Table 3. Financial execution per Member State, programming period 2007-2013

Source: Author processing data from Rural Development in the European Union - Statistical and economic information – 2012, European Commission

Regarding the degree of access to funds, we find the highest value for Lithuania (979.739.000 €). If we make a calculation by reference to the total amount, Latvia has the highest level of access to funds, it is over 60%, but also the other countries have similar percentages of 59.1% for Estonia and 55.5% for Lithuania.

In all three countries, the largest high grade access occurs for Technical assistance, 511, where all States have access to 100%.

In Estonia, the highest degree of access it was registered for Axis 2, Improving the environment and the countryside that is 39,83% of the total funds accessed, with a value of 170.529.000. Measure 214, Agri-environment payments was the most accessed under this axis. For Axis 1, the percentage of accessing funds is 35,42% with the amount of 170.529.000€. In this axis, to measure 121 were collected the most funds, 93.704.000 €. From Axis 3 were accessed funds worth 57.194.000 €, respectively 13.36% of the total funds paid to this country. Within Axis 3, for Measure 322 Village renewal and development has achieved 57,54% of these funds and for Measure 312 were received funds of 24.257.000€. For Axis 4 were accessed funds worth 29.925.000€ representing 43,7% of the total funds allocated to this axis.

In Latvia, as in the case of Estonia, the highest level of access has registered for Axis 2, where there were received 285.629.000 €, respectively 44,66%. Under this axis, measure 212, Payments to farmers in Areas with Handicaps, other than Mountain Areas was the most accessed and managed to bring 157.476.000 € that is 55,13%. For Axis 1 Improving the Competitiveness of the agricultural and forestry sector were charged 238.576.000 €, respectively 37,3% of all funds accessed and the harnessed measure is 121, which brought a total of 164.595.000 € equivalent to 68,99% of the total axis. For Axis 3, Latvia has received 91.778.000€ representing 14,35% of the total funds collected. The most used measure was 321 Basic services for the economy and rural populations with the amount of 47.355.000€. For Axis 4 have received funds amounting to 10.050.000€.

As in the other two countries, we can say that in Lithuania the most accessed measure under Axis 1, has been 121, with an amount of 264.342.000€, respectively 54.55% of total axis. Axis 1 has the highest percentage (49,46%) and a value of 484.555.000€ funds received. Under Axis 2, the most accessed measure has been 212 who received an amount of 204.597.000€ that is 51,32%. For the Axis 3, the most used measure was 312, which received a total of 16.966.000 € out of a total of 41.287.000€. From the axis 4 were used 13,8% of the funds available on this axis, respectively the amount of 14.898.000€.

## **6. In conclusion**

The three countries have experience in implementing EU funds considering that benefited from rural Development Plans in 2004-2006 and SAPARD.

For rural development policy at EU level through EAFDR was allocated a budget of 96,3 billion euro for the period 2007-2013. The total amount of funds for the three countries compared in this article is 3.543.905.000 euro, allocated as follows: Estonia have funds amounting to 723.737.000 euro, Latvia (1.054.374.000€) and Lithuania received 1.765.794.000 euro.

Lithuania is the largest country in the group of the three Baltic countries with an area of 65.300 km<sup>2</sup>, GDP recorded the highest value (32.781,8 millions of euro) and has the largest number of the population (3.007.758). However, the highest value of the indicator GDP /person we observe in Estonia (12.688 euros / person). Lithuania

recorded the highest number of people working in the sector (141.500 people). The farms are less in Estonia (19.610), in Latvia are 83.390 farms and in Lithuania are more farms (199.910).

Regarding the degree of access to funds until September 2012 we find the highest value for Lithuania (979.739.000€). If we make a calculation by reference to the total amount results that Latvia has the highest level of access to funds, it is over 60%, but and the other countries have similar percentages of 59.1% for Estonia and 55.5% for Lithuania.

In Estonia, the highest degree of access it was registered for Axis 2, Improving the environment and the countryside that is 39,83% of the total funds accessed, with a value of 170.529.000. Measure 214, Agri-environment payments was the most accessed under this axis. In Latvia, as in the case of Estonia, the highest level of access has registered for Axis 2, where there were received 285.629.000 €, respectively 44,66%. Under this axis, measure 212, Payments to farmers in Areas with Handicaps, other than Mountain Areas was the most accessed and managed to bring 157.476.000 € that is 55,13%. As in the other two countries, we can say that in Lithuania the most accessed measure under Axis 1, has been 121, with an amount of 264.342.000€, respectively 54.55% of total axis. Axis 1 has the highest percentage (49,46%) and a value of 484.555.000€ funds received.

## CONCEPTUAL DELIMITATIONS ON SUSTAINABLE DEVELOPMENT

**Ienciu Ionel-Alin, Popa Irimie Emil**

*Accounting and Audit Department, Faculty of Economics and Business Administration, Babeş-Bolyai University, Cluj Napoca, Romania*

[alin.ienciu@econ.ubbcluj.ro](mailto:alin.ienciu@econ.ubbcluj.ro),

[irimie.popa@econ.ubbcluj.ro](mailto:irimie.popa@econ.ubbcluj.ro)

**Abstract:** *Sustainable development is a model for resource use meant to satisfy human needs, without polluting the environment, so that these needs can be satisfied not only in the present, but in the future as well. It is a concept of nowadays with no generally accepted definition, placing environment first and foremost, aiming at implementing the environmental policies in all structures and at all economic levels. Within the present study we have aimed at creating a conceptual delimitation on sustainable development, sustainability and social responsibility, concepts of present interest, that tend to become a mystery for the academic community and practitioners by their variety and complexity of approaches. During our scientific endeavor we believe that social responsibility is the foundation of sustainable development. Sustainable development is a concept used especially at macro-economic level, while social responsibility is used at entity level and incorporates the economic, environmental and social dimension, which has a voluntary character and tries to respond to the information needs of the society and other stakeholders. Sustainability at the entity's level is the goal or final objective of sustainable development – satisfaction of present needs without compromising the possibility for future generations to satisfy their own needs, while social responsibility is an intermediate phase of sustainability wherein entities try to balance the economic, social and environmental dimension. Thus, we can state we include ourselves within social corporatism, slightly close to social institutionalism, which is characteristic to developed countries, giving a particular importance to social contract and relations between entity and society. We believe that in Romania, a POSDRU funded project should be regarded as a legal person with social values, which must be based on sustainable development and to promote, besides legal liability of automatically deriving legal contract, social responsibility, which resulting from its relationship with society in which it is implemented, and within these relations, environmental protection represent a major social responsibility of any kind of project.*

**Key words:** sustainable development, social responsibility, sustainability, conceptual approach, environmental economy, POSDRU funds

**JEL Classification:** M19

### 1. Introduction

The economy of environmental protection implies the achievement of a sustainable, compatible ecological development, linking humans, economy and environment, believing there is a tight link between natural disasters, environmental mutations and the economic development of each state.

Sustainable development is a model for resource use meant to satisfy human needs, without polluting the environment, so that these needs can be satisfied not only in the present but in the future as well.

The meaning of sustainable development is given precisely by the endogen model of reconciliation between man and nature. The developing countries need to accelerate their growth rate, but within strategies considering the natural physical environment, by means of using less energy intensive and non-polluting technologies. The countries with a developed potential from a financial, economic, human and technological point of view have multiple chances of projecting a sustainable development.

The main objective of our study is to offer a clear image on the concepts of *sustainable development*, *sustainability* and *social responsibility*, concepts that are of present interest, which by a variety and complexity of approaches tend to become a mystery both for the practitioners and the academic community.

## **2. Research methodology**

The use of certain research methods and instruments was necessary when conducting this scientific approach in order to facilitate the scientific research process (Mustata, 2008: 13). From the point of view of research currents, the present paper aligns to the main research current, having a positive and constructive touch. As far as the research typology is concerned, the study is a theoretical, fundamental research. Amongst the research methods specific to qualitative research we have used as part of this scientific approach we would mention comparative analysis and non-participative observation.

## **3. The Concept of Sustainable Development**

„Sustainable development is loyalty towards the future”(Pearce et al., 1989: 20). According to Tietenberg (Tietenberg, 1984), if a project maximizes the updated value of benefits, but incurs losses for the future generations, a quota from the gained benefits should be put aside in a compensation fund for „inter-generations”. Sustainable development is probably the key element of the 21<sup>st</sup> century humanity. It is a difficult to grasp concept, mainly due to this notion's richness, diversity and complexity. There are more than 100 definitions in use and various persons understand in different ways this term, depending on their political and ideological convictions (Hibbitt, 2001). Nevertheless, there is no generally accepted definition of sustainable development, which is a problem for practitioners, but also an attraction point for academicians (Moneva et al., 2006: 122).

Sustainable development has gained a particular place with the issue of the Brundtland Report in 1987 and the acknowledgment of the greenhouse effect, the most widely accepted definition of sustainable development being the one proposed in this report. The Brundtland Report defines sustainable development as the satisfaction of present needs, without compromising the capacity of future generations to satisfy their own needs (WCED, 1987). The Agenda 21 defines sustainable development as that development which doesn't destroy or compromise the ecological, economic and social basis that continuous development depends on (WTOEC, 1995).

Sustainable development doesn't consider exclusively the environmental aspects. The reference document for the **World Summit on Sustainable Development** in 2002 speaks about the independence and mutual support of the pylons of sustainable development such as economic development, social development and environmental protections. Certain researchers have mentioned in time, during the

various international forums the existence of the fourth pylon of sustainable development, i.e. cultural diversity.

The uniqueness of sustainable development as concept consists in the attempt to include the environmental and inter-generations dimensions in the neoclassical theory of economic development (Purvis and Grainger, 2004, pp. 1). This has inevitably led to the development of an approach which is meant to work within the existing production and distribution economic system, placing emphasis on the use of economic instruments in order to secure the proposed results. Thus, sustainable development is a concept combining the postmodernist pessimism on the domination of nature and the illuminist optimism on the possibility to reform human institutions (Dresner, 2002).

Critics on this concept have not delayed to occur:

- John Baden believes that the notion of sustainable development is dangerous, because the consequences of using such concept are procedures of unknown or potentially dangerous effects (Baden, 2008);
- The term „sustainable development" is criticized for its lack of clarity, considered an absurd term, or more likely, so vague that it means nothing, proving contradictory: „The term is more charming than significant [...]" (Ferry, 2007: 78);
- Sustainable development hides a protectionism practiced by developed countries in order to hinder the development of other countries. Sustainable development is a pretext for protectionism and is considered a perfect help for capitalism (Brunel, 2008);
- The „decrease" is a political and economic ideology, pleading for a gradual decrease of the economic production. The supporters of this ideology believe that the decrease of production is the only solution for the current environmental problems the humanity is facing, and that sustainable development is not possible (Clémentin and Cheynet, 2008).

In our opinion, although sustainable development can be criticized for lack of clarity and difficulty of being put into practice or maybe, on one side hides the protectionism of developed countries, it represents an acknowledgement of the fact that the planet's natural resources are limited and that the natural environment shows a limited capacity for waste absorption. These limits, once surpassed, compromise the capacity of future generations to satisfy their own needs. Thus, sustainable development, before everything, is a way of performing our activities, day by day, a way of acting such as to ensure a balance between the planet's natural limits, the satisfaction of present needs and the satisfaction of future needs.

The introduction of the sustainable development dimension within POSDRU funded projects is a necessity in order to increase the sustainability of projects because as sustainable development seeks to promote a more efficient in terms of greener and more competitive use of resources.

#### **4. Sustainability Development versus Sustainability**

In the Anglo-Saxon literature the term used is "sustainable development". In Romanian, the translations used are both "durable development", as well as the more forceful „sustainable development". The last translation derives from the word „sustainable", which in turn comes from „sustain"- to support (oneself) and „able"-capable. Henceforth two perceptions of this concept leading to the same result, that

of „development within the limits of the *supportcapacity*" (Petrișor, 2002: 2; Conway and Barbier, 1988: 654):

- „*capacity to sustain*"- the capacity of natural resources to sustain unlimitedly the development of the human society, a use of natural resources within the limits of the support capacity;
- „*capacity to self-sustain*" - refers to a development that would ensure on one side, the evolution of the human social and economic system without affecting the existence of future generations, and on another side, it suggests the idea of an evolution within the limits of the support capacity

Sustainability is a concept referring to a process of equal allocation of resources, at global level. The equity or correctness derives from a rational and responsible distribution of resources and from the existing opportunities in the present and future generations (O'Dwyer and Owen, 2005; Dragomir, 2008: 2).

There are also certain confusions regarding the terms "sustainable development" and "sustainability". The sustainable development and sustainability have been and are still considered synonyms by many researchers, despite the fact that Brawn Lester was writing in 1988 about sustainability: „The concept of sustain capacity is used by biologist for many years, but until recently, it has been rarely considered by economists" (Lester, 1988: 34). Sustainability, in a large sense, means the capacity to maintain certain process and is more frequently used in connection to biological and human systems, in other words, sustainability is not a concept specific for the field of economics. Starting with 1980, the idea of human sustainability starts to be more and more associated with the integration of the three spheres specific to sustainable development: economic, social and environmental. In 1989, the United Nations Brundtland Commission defines sustainability as the satisfaction of present needs, without compromising the future generations' capacity of satisfying their own needs (United Nations, 1989), definition which the Bruntland Commission used in 1987, in its report called *Our joint future*, in order to define the concept of sustainable development.

Foreign literature (Schaltegger et al., 2006) highlights that a distinction must be made at entity level, between „sustainability" and "sustainable development". In order to conform to the principles of sustainable development, an entity must establish a set of objectives and targets it wishes to achieve, thus heading towards sustainability. We can therefore visualize *sustainability* as the final objective an entity would wish to achieve, the statute or situation it aspires to, and *sustainable development* as the process by means of which human activity heads for sustainability or maintains this statute (Hibbitt, 2001). It results that sustainability is a specific concept at entity level, frequently used at micro-economic level, while sustainable development has a much wider inclusion area, and the concept is used at macro-economic level. We are thus talking about sustainable development as a principle or objective, at national or international level, and sustainability as an objective at entity's level.

In conclusion, although some researchers consider sustainability as a synonym for sustainable development, we believe sustainability to be a specific concept at entity level, frequently used at micro-economic level and associated with the integration of the three spheres specific for the sustainable development: economic, social and environmental, whilst sustainable development is an objective or principle used at macro-economic level.

In POSDRU funded projects, sustainability is a key criterion in awarding funding that should be followed for the entire implementation of the project and monitoring how the project is constructive for natural and social context in which it is implemented to generate new ideas and services when the grant ends<sup>2</sup>.

### **5. Sustainable Development versus Social Responsibility**

Similar to the globalization or sustainability, social responsibility is a complex concept, with much significance which, as removed, new meanings of this concept come out (Shanahan, 2001). As a result, within the entities and the academic world there is an uncertainty regarding the way social responsibility is defined. Certain researchers go so far as to believe that there is no definition of this concept whatsoever (Jackson and Hawker, 2001). The problem is more likely represented by the fact that there is a large variety of definitions, influenced by specific interests and as a result, hinder the development and implementation of the concept (Van Marrewijk, 2003).

Alexander Dahlsrud (Dahlsrud, 2007) identifies during a content analysis 39 definitions frequently used, five dimensions of social responsibility:

- Environmental dimension – natural environment;
- Social dimension – relation between entity and society;
- Economic dimension – social, economic and financial aspects;
- Stakeholders dimension – group of users;
- Voluntary dimension – actions not having been prescribed by the law.

By combining these dimensions a variety of definitions and visions on sustainable development is resulting from. The most frequently used definition in the specialized literature for representing the concept of social responsibility is issued by the European Commission, definition incorporating all five dimensions mentioned above: Social responsibility is a concept that entities use to voluntarily integrate social and environmental concerns within the economic operations and their interaction with the stakeholders (European Commission, 2001).

Social responsibility is a *brilliant* term (Göbbels, 2002: 96) debating the relations between the business environment and society. Depending on how it regards the entity and the connection between the entity and society, there have been five approaches identified on social responsibility, based on different political specters (Carter and Burritt, 2007):

- *Fundamentalism, neoclassicism or owners / shareholders approach* is the approach corresponding to the right hand political spectrum stating that entities are purely legal creations and not social institutions, as social responsibility is limited to paying taxes and creating new jobs (Klonoski, 1991; Moir, 2001);
- *Social corporatism or users approach* is based on the fundamentalist approach wherein the purpose of a corporation is to create profit, by admitting and accepting at the same time the social aspects arising during the actions taken by the entity. This approach is a melting between the fundamentalist belief and the social institutionalism. One of the first supporters of this approach, Druker, claimed that in order to pursue their own interest, entities should be concerned

---

<sup>2</sup> National Centre for the Development of Vocational and Technical Education POSDRU Informative note, november 2009

by society and undertakes some of the responsibility appearing beyond the traditional economic areas. Social corporatism considers sustainable development and social responsibility as business strategies, determining entities into becoming more receptive to the changes occurring in their environment of operation (Dentchev, 2005; Brown and Fraser, 2006);

- *Social institutionalism* approaches the entity as a social institution with social responsibilities, necessary for the creation and promotion of an open and transparent democratic society (Klonoski, 1991; Brown and Fraser, 2006). This approach is based on the social contract and represents the middle ground between fundamentalism and criticism (Gray et al, 1988). According to this approach, the entity should respond to the society's needs and demands and must be fully responsible before it (Gray et al, 1995). Social institutionalism is the dominant approach in the current academic debates, based on the entity legitimacy theory and stakeholders or user theory. (Norris and O'Dwyer, 2004);
- *Moralism* is an approach close to social institutionalism, but a little more philosophical, directing social responsibility towards philosophy, thus incorporating moral and ethical virtues. The entity represents a legal person, intangible, responsible (Klonoski, 1991), which needs to be treated just as a private person, having the possibility to make it accountable for actions taken. Palazzo and Scherer (Palazzo and Scherer, 2006) believe that the entity's moral legitimacy is the foundation of social responsibility;
- *Critical theory* represents a new approach corresponding to the left hand political spectrum, bringing about a critical vision over the other approaches presented above. For the critics, social responsibility is a potential victim of daily activities, a mystery, where meanings are lost among the members of the society (Brown and Fraser, 2006), and the social, ethical and environmental reports are means of disinformation or ways of washing out responsibilities (Brown and Fraser, 2006).

Considering three of the five dimensions (economic, environmental, social) we raise the following question: what is the difference between sustainable development and social responsibility? In order to answer such question, we have analyzed the study conducted by Ebner and Baumgartner (Ebner and Baumgartner, 2006), including 43 articles published between 1998 and 2006, with the subject of social responsibility and sustainable development. The authors have identified the following treatments applied to social responsibility:

- Social responsibility is interpreted as the social dimension within the concept of sustainable development. In this case, the responsibility of an entity includes social, economic and environmental responsibility (Zwetsloot, 2003; DesJardins, 1998);
- Social responsibility is the foundation or base of sustainable development. Sustainable development is a concept used at large scale, macro-economic level, while social responsibility is only used at entity level, expressing the sustainable orientation of the entity. There are small differences between sustainability and social responsibility at entity level: sustainability focuses on creating value, environmental management, ecological production system and human capital management, while social responsibility is associated to certain aspects of communion between individuals and entities (Dawkins and Lewis, 2003);

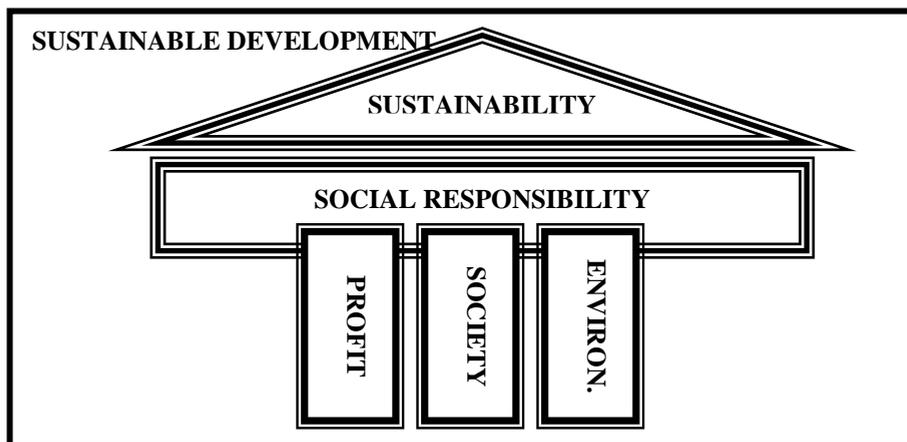

- Social responsibility is treated as a tridimensional model, synonymous with sustainable development (Cramer, 2004). This trend comes from the American researchers and entities tempted to replace the concept of sustainable development with the concept of social responsibility.

To be sustainable, POSDRU funded projects should increase social responsibility in the communities in which they are implemented and to create added value to the society in which are implemented on a long time orizot.

## **5. Conclusions**

Sustainable development is a concept of present interest at national, European and international level, a new philosophy of development, a fundamental objective towards which European countries aspire to reach.

During our scientific endeavor we believe that social responsibility is the foundation of sustainable development. Sustainable development is a concept used especially at macro-economic level, while social responsibility is used at entity level and incorporates the economic, environmental and social dimension, which has a voluntary character and tries to respond to the information needs of the society and other stakeholders. Sustainability at the entity's level is the goal or final objective of sustainable development – satisfaction of present needs without compromising the possibility for future generations to satisfy their own needs, while social responsibility is an intermediate phase of sustainability wherein entities try to balance the economic, social and environmental dimension (Figure 1). Sustainability and corporate social responsibility (CSR) are concepts often used in the same context. Nevertheless, sustainability is a complex concept aiming to promote long term growth, for all forms of available capital (financial, natural and social), and corporate social responsibility is a more narrow concept, focused on short term problems and activities such as observance of legislations, philanthropy and the improvement of working conditions. In general, we could say that many entities claim to be responsible towards the society, but only few would claim to be actually sustainable.

**Figure 1.** Representation of the relation between sustainable development, sustainability and social responsibility at entity level  
Source: author's projection

Thus, we can state we include ourselves within social corporatism, slightly close to social institutionalism, which is characteristic to developed countries, giving a particular importance to social contract and relations between entity and society.

We believe that in Romania, a POSDRU funded project should be regarded as a legal person with social values, which must be based on sustainable development and to promote, besides legal liability of automatically deriving legal contract, social responsibility, which resulting from its relationship with society in which it is implemented, and within these relations, environmental protection represent a major social responsibility of any kind of project.

**Abstract:** *Convergence may be considered a central issue of the current economic literature, and not only, concentrating upon income distribution within different economies, but also focusing on different aspects of polarity and inequality that characterize especially the emerging economies. Testing convergence within economies may serve as a useful instrument for the validation of the economic growth models. While convergence was considered a defining element of the neoclassical growth models, the majority of the new endogenous growth models argue in favour of divergence across different economies. Testing convergence among European Union is even more challenging due to the high degree of heterogeneity that characterizes these economies. The recent accessions with ten new countries in 2004 and with another two in 2007 were considered only the first step towards assuring a sustainable convergence and finally adopting a common currency-the euro. A series of empirical studies concentrated upon testing convergence among EU, using as benchmark the real convergence quantified by the level of GDP/capita as an indicator for the living standards of every economy. The most popular approach rely on Beta and Sigma convergence, the first one being an indicator of the GDP/capita dispersion between different economies, and the later one being an estimator of the reverse relationship between GDP/capita and its initial level. The main purpose of this paper is to test Beta converge among the new EU member states, in order to obtained more information about the fact whether the poor countries are trying to catch-up with the more developed ones. Also Beta convergence indicator embodies useful information about conditional and unconditional convergence, two leading hypothesis within the neoclassical and endogenous growth models. For Beta convergence hypothesis to be valid it should be taken into consideration a "catch-up" mechanism over a longer period of time and a set of elements that are inter-correlated with the main objective of reducing disparities among economies. However we also have to take into consideration the fact that these elements may be influenced by temporary shocks that may have a decisive impact upon their short time performance.*

**Keywords:** Beta convergence, real convergence, emerging economies, growth models.

**JEL classification:** O11

## 1. Introduction

*Conducting an objective analysis upon the criteria, policies and instruments used in the convergence process by the new European Union member states may be considered extremely challenging. The correct analysis and interpretation of convergence nowadays it's considered to be very important and thus the study of its impact beyond the general policies imposed by the European Union through the nominal convergence criteria could highlight the mutations across economies and especially the correlations between them. During time, a series of papers discussed and quantified using different instruments the degree of convergence between economies. If we were to classify the main trends related to the process of real convergence across the Central-Eastern economies we may distinguish between the following categories (Ingianni, 2010):*

- *The first category takes into consideration time series variables regarding the evolution of GDP/capita for the purpose of testing convergence using some standard measures like Sigma and Beta convergence. Convergence in terms of Sigma and Beta indicators is an extremely debated subject and many studies concentrate their empirical research upon these two aspects. A representative article is the one elaborated by Ingianni A., Vaclav Z. (2007) that using quarterly data regarding GDP/capita evolution obtained significant results for real convergence across European Union both for Sigma and Beta convergence. Bruggeman and Trenkler (2007) also investigates the degree of convergence across Hungary, Czech Republic and Poland in order to test the integration effects upon GDP/capita across European Union and also upon a group of Mediterranean states over a longer period of time. The used instruments are the unit root tests that allow the analysis of structural breaks. The general conclusion of the study is that Czech Republic and Hungary stochastically converge towards the group of Mediterranean states, while only Hungary converges towards EU average.*
- *The second trend uses different economic indicator for testing convergence among different economies. Kocenda, (2001), Kutan and Yigit, (2004) concentrate their research in this field. Kocenda (2001) analysis the performance of Central-Eastern economies like Czech Republic, Slovakia, Lithuania, Latvia, Estonia, Hungary, Poland, Romania, Bulgaria and Albania using monthly data from 1991 to 1998. The obtained results indicate convergence across these economies, but its intensity is highly influenced by the set of included variables and also by the group of countries. The Baltic countries registered high convergence rates, being at the same time the most homogenous group. The convergence hypothesis was validated across all states regardless of their initial condition, institutional background or privatization techniques used by every economy. Kutan and Yigit (2004) use an endogenous model of economic growth in order to test the impact of European Union integration upon productivity growth and convergence. The authors use a derivate version of this model that allows them to incorporate new estimation techniques for obtaining more precise results. The group of countries taken under observation is formed by Spain, Portugal, Austria, Sweden and Finland. The obtained results are in favour of convergence across these states.*
- *The third trend focuses upon eastern economies in the post-liberalization period. Dobrinsky (2006) quantifies the connection established between real*

and nominal variables involved in the dynamics of exchange rate (Balassa–Samuelson effect). There are three main discussed directions namely: testing the degree of convergence between the new member states and the EU average, the analysis of the economic fundamentals that support the catch-up process and testing the Balassa-Samuelson effect across new EU member states. The results confirm the convergence hypothesis for that particular group of countries.

## 2. A short insight into Beta convergence analysis

*In what concerns the catch-up process between different economies there is no general consensus both at theoretical but also at empirical level regarding the convergence concept. The methodology used is influenced in the first place by the group of countries taken under observation, the time dimension but also by the data availability. The literature review distinguishes three main concepts that could be associated with the concept of Beta convergence:*

### 2.1 Absolute or un-conditional convergence

*The starting point of this theory is without any doubt the neo-classical growth models that predict convergence across economies towards their steady state (the same for all economies), convergence that it's influenced by a series of factors like the growth rate of population, saving rate and degree of capital depreciation. Barro and Sala-i-Martin (1992) developed a general framework that allows highlighting the main connections between the neoclassical growth model and the catch-up hypothesis. The general representation of the model is the following one:*

$$\frac{1}{T} * \log\left(\frac{Y_{i,T}}{Y_{i,0}}\right) = \alpha - 1/T(1 - e^{-\beta T}) * \log Y_{i,0} + \gamma X_{i,t} + u_{i,t} \quad (1)$$

where  $Y_{i,T}$  denotes the real GDP/capita of country  $i$  at time  $T$ ,  $Y_{i,0}$  is considered the initial GDP/capita of country  $i$ ,  $X_{i,t}$  represents the set of exogenous variables that may have an impact upon the evolution of GDP/capita,  $u_{i,t}$  is the error term,  $\alpha$  is the constant,  $\beta$  is the convergence coefficient that it has to be estimated and  $T$  is the time horizon for the data included in the model.

Barro and Sala-i-Martin use this model in order to test Beta convergence across United States. The model is non-linear in Beta. They obtained a value for Beta of 0,0175 for the time period between 1880-1988 and 0,0224 for the time period between 1880-1990. The positive value of this coefficient indicates that for that particular group of countries the Beta convergence hypothesis is confirmed. This hypothesis was also validated for the OECD member states. The results changed when the sample was extended to the group of 98 economies from all over the world. In this case the convergence hypothesis was infirmed. Taking all these points into consideration, we may conclude that the absolute convergence hypothesis is confirmed only for a group of countries with homogenous characteristics and with similar steady states for a long period of time. Furthermore, it is extremely challenging to quantify absolute convergence across world economies, the majority of studies concentrating upon conditional convergence.

### 2.2 Conditional convergence

As we stated before, neoclassical growth models argue in favour of the fact that economies that do not convergence to the same steady state will not achieve long

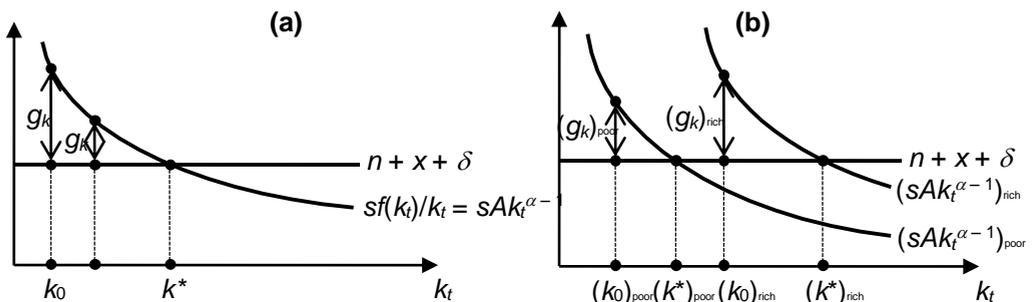

time convergence. A series of empirical studies concentrated upon convergence analysis identified a reverse relationship between the initial level of GDP/capita and its growth rate. In order to test conditional convergence between different economies it is essential to determine those variables known as proxy for long-term economic growth. During time a series of economic, political and institutional variables were investigated in order to establish their impact upon the economic growth process. The study developed by Mankiw, Romer and Weil (1992) provides the framework for what we call today *conditional convergence*. Starting from Solow-Swan growth model, the authors divided the investment component into two additional variables namely: a) investments that improve work productivity by improving the physical capital component; b) investments that improve work productivity by improving the human capital component (Daly,V., 2010). This subdivision of the investment component allows economies to converge towards different steady states. The model may then be summarized as:

$$\log\left(\frac{y_i(T)}{y_i(0)}\right) = A_0 + A_1 \dot{k}_t + A_2 \dot{h}_t - \beta \log(y_i(0)) + \varepsilon_i \quad (2)$$

where  $\dot{k}_t$  and  $\dot{h}_t$  are the tendencies to invest in physical and human capital,  $y_i(T)$  is the GDP/capita for time T,  $y_i(0)$  is the initial GDP/capita,  $\beta$  is the coefficient for convergence,  $\varepsilon_i$  is the error term.

The methodology developed by Mankiw, Romer and Weil (1992) revealed the fact that economies tend to converge towards their steady states at a common growth rate but this steady state may differ between countries.

Conditional convergence is limited by the fact that economies tend towards reaching the same steady state. To illustrate this situation we concentrate upon a simple example. We consider two economies: one rich country and a poor one, each with different saving rates. Clearly the saving rate is much higher within the rich country, which leads to a capital steady state much higher than in the poor country. In this case rich economies starts from a much higher level of capital and this would lead to a higher growth because it tends towards a different steady state than the poor economy. In this case economies will record different convergence trends. A comparative approach towards these two types of convergence namely absolute and conditional convergence is illustrated in the figure below.

**Figure 1.** Absolute vs. Conditional convergence

### 2.3 Convergence clubs

Quah (1996,1997) in a series of studies that concentrates upon Sigma and Beta convergence argue in favour of the fact that the previous models are not clear enough in testing the hypothesis whether the poor economies will remain at the same level over a long period of time or by contrary will try to align to the standards imposed by the rich ones. Quah promotes the concept of „convergence clubs”, concept used for the first time in the literature by Baumol (1986). This concept underlines the fact that a group of countries with similar initial conditions will register convergence trends in what concerns their GDP/capita level. An interesting research on the hypothesis of regional convergence across European Union is the one conducted by Fischer and Strirbok (2006) that using spatial econometric models relates the concept of club convergence with the one of spatial heterogeneity. The convergence hypothesis is tested for a group of 256 European regions over a time horizon between 1995 to 2000. The main conclusions follow two directions. In the first place the standard regression model proposed by Barro (1992) is rejected, and secondly there is a heterogeneous convergence trend across European Union regions. Heterogeneity implies both income level but also steady states.

### 3. Beta methodology

Whether this indicator is used to validate the convergence hypothesis within an individual economy or is applied to a group of countries, Beta convergence may be determined using the following formula:

$$T^{-1} \ln \left( \frac{y_t}{y_0} \right) = \alpha + \beta \ln(y_0) \quad (3)$$

where the left side of the equations represents the average growth rates of GDP/capita logarithm between t=0 and t=T,  $\alpha$  represents the constant and  $\beta$  is the variable that we want to estimate.

In order to test for Beta convergence we choose the group of the new member states of European Union that accede in 2004 and 2007, and are whether in the case of being adopted the single currency euro or on the path towards it. The time horizon range between 1992 and 2011, the data source being Eurostat.

**Table no.1** The evolution of the variables included for testing Beta convergence

Country	Initial GDP/capita (1992)	GDP/capita (2011)	Growth rates of GDP/capita 2011/1992
<b>Bulgaria</b>	6520,974	11792,60891	1,808412196
<b>Czech Republic</b>	14407,27	24011,01701	1,66659034
<b>Cyprus</b>	18918,77	26045,55539	1,376704479
<b>Estonia</b>	7532,002	18129,01521	2,40693181
<b>Latvia</b>	6109,658	13773,49335	2,254380417
<b>Lithuania</b>	9278,041	16876,70558	1,818994503

Source: Eurostat, 19.03.2013

In what concerns the evolution of GDP/capita, this indicator presents a clear image of the manner in which this countries react to the conditions imposed by EU membership but also of the effects of the economy dynamics. Comparing year 1992 with 2011 the general economies ranking is almost the same during time, countries with high value of GDP/capita being Cyprus and Slovenia at the opposite pole being situated Romania and Bulgaria. The differences in what concerns the GDP/capita may be influenced by o series of factors, the most important ones being related to the political, economical and institutional framework that characterize every economy. We should also notice the fact that this particular group of emerging economies is defined by different historical and also geographical backgrounds that could be considered a source of differences in the levels of GDP/capita. If we were to make a general classification of these economies, the following dichotomy could be applied:

- Baltic countries: Estonia, Lithuania, Latvia;
- Ex members of Czechoslovakia: Czech Republic and Slovakia;
- Ex members of Yugoslavia: Slovenia
- Islands: Malta and Cyprus
- Countries with soviet influence: Romania, Bulgaria, Poland and Hungary.

Also we should take into consideration the fact that the recent financial crisis has triggered dramatic change upon the entire economic system, enforcing a series of adjustments both at national but also at international level across EU.

**Table 2.** The correlation between the initial GDP/capita and the level of GDP/capita

	PIBILOG	DPIBCLOG

DPIBCLOG	-0.1363247706396561	1

Source: Authors calculations based on Eurostat data.

The results for the correlation between the initial GDP/capita and the level of GDP/capita for the new member states is in line with the neoclassical growth models forecast. According to these models convergence between countries is considered to be the rule, while divergence is perceived as a transitory phenomenon.

**Figure 2.** Beta convergence across new European Union member states  
Source: Authors calculations based on Eurostat data.

There are a series of empirical studies that concentrate upon the issue of Beta convergence in what concerns the level of GDP/capita among new EU members but also between this group of countries and EU average. A short description of the used methodologies but also the main results of this research are listed in the table below.

**Table 4.** Studies upon Beta convergence across EU members states

Authors and article title	Methodology	Time horizon and variables included	Results
Varblane and Vahter (2005), "An analysis of the economic convergence process in	Beta and Sigma convergence e-panel regression model	1995-2004 Initial GDP/capita ratio The ratio of real GDP/capita of the countries to GDP/capita at the EU level.	For the analyzed period the un-conditional Beta

transition economies”	Beta convergence	1993-2004 Dependent variable: Final GDP/capita / Initial GDP/capita Explanatory variable: average annual growth rate of real GDP per capita	convergence hypothesis is confirmed. The Beta convergence hypothesis is confirmed for all the 8 CEE countries within the sample in what concerns their income levels.	
Matkowski and Prochniak (2007), ”Economic convergence between the CEE 8 and European Union”	Beta and Sigma Convergence-panel data analysis for Beta convergence	1992-2006 Annual GDP growth rates regressed against the GDP levels from the previous year.	The main conclusion of the study is that the countries diverge during 1992-1997 but converge afterwards

The mechanism of convergence was constant over time. The EU 27 countries converge at a rate of 5%/annum while the EU 15 converge

Source: Authors interpretation.

The majority of the studies that concentrate upon testing Beta convergence across European Union and especially among the new member states of EU confirm de convergence hypothesis. After testing Beta convergence across new Member States of the European Union it may be concluded that there is clear evidence to support this hypothesis corresponding to the value of Beta coefficient of -0.32. Even though the value is a little too high it certainly validates the convergence in what concerns the GDP/capita level across new member states. Beta convergence test will be applied only for all the 12 new EU member states, their division in subgroups would lead to the formation of small samples of countries whose inclusion in the model would provide irrelevant data both statistically and economic .

## **5. Conclusions and future research**

The main purpose of this study was to test Beta convergence hypothesis among the new EU member states based upon their GDP/capita. The obtained results confirm the existence of convergence across this group of states, so there is a general *catch-up* tendency between them. The validation of these results is also due to the fact that one of the main objectives of the European Union is to reduce disparities between the economies of the member states through a series of structural and regional policies. In order to develop a more profound analysis of the convergence process across economies, one should take into consideration testing also Sigma convergence, relying on the fact that Beta convergence is a necessary but not a sufficient condition for testing Sigma convergence. This aspect would be developed in future research. In order to achieve a sustainable degree of convergence an economy should concentrate upon a mixture of different economic, political, social and institutional factors that all work together towards achieving the same goal. A high degree of convergence between economies could also contribute to high levels of economic growth and development.

Another challenge would be to test the hypothesis whether these countries converge also towards the average of all EU member states or towards the average of Euro zone. This analysis would provide future information about the efforts of the new member states to align to the general trends imposed by European Union.

## EMPIRICAL STUDY REGARDING THE DETERMINING FACTORS OF THE ROMANIAN COMPANIES COMPETITIVENESS

**Moldovan Nicoleta-Claudia, Lobonț Oana-Ramona, Nicolescu Cristina-Ana**  
West University of Timisoara, Faculty of Economics and Business Administration,  
Timisoara, Romania

[nicoletamoldovan2004@yahoo.com](mailto:nicoletamoldovan2004@yahoo.com)

[lobont\\_oana@yahoo.com](mailto:lobont_oana@yahoo.com)

[cristina\\_nicolescu81@yahoo.com](mailto:cristina_nicolescu81@yahoo.com)

**Abstract:** *The complexity of the concept of competitiveness lies in the fact that the term is used in various levels of aggregation, allowing the generation of its different meanings at microeconomic, mezzo-economic and macroeconomic level.*

*This study is focused on the concept of company competitiveness, on the relevant factors in order to analyze and explain the advantage of competitiveness for a company in regard to another, as well as the dimension and intensity which it uses the sponsors' capital, the organizational capital, the human capital, the innovational capital and the capital represented by the customers portfolio. Secondly, using the questionnaire method as a research method, the objective of this paper is to provide some empirical evidences designed to assess the factors determining the Romanian company competitiveness on the competitive market. By using an initial dataset of 300 companies, which are part of the 14 fields of activity provided in the activity classification of the national economy, Reviewed NACE 2, we have made their classification on size classes, taking into account as classification criteria the number of employees, the annual net turnover and the value of the total assets held, then testing the opinions of the managers from the selected sample concerning the factors determining the competitiveness of the companies they manage. According to the results, the analysis of the sample structure reflects the control of microenterprises followed by the small and medium sized enterprises. The manner of administration and organization and the quality of the employed human factor are influenced by the company dimension and position held on the market. We consider that the managers of the small size companies, as well as the ones from the provided sample, rely on a preponderant intuitive management, they deal the administered businesses based on the spur of the moment inspiration, make decisions subjectively not starting from objective economic criteria, being concerned only with the management of the current problems. Since they aren't the beneficiaries of a managerial education, they don't possess the necessary competences to focus on the elaboration of certain strategies by which to provide competitiveness and performance on the long-term. However, the managers' training and competence influence on the identification and use of the factors which are able to provide the company development.*

**Keywords:** *company competitiveness; sponsors' capital; organizational capital; human capital; innovational capital; capital represented by the customers portfolio.*

**JEL classification:** D22; L25; O12.

## 1. Theoretical Background

Given the fact that competitiveness reflects the comparative advantage which a company holds in regard to the other competitors at a certain moment on the competitive market, which changes in time and space, then, in their turn, the determining factors of competitiveness are differentiated with respect to the selected analysis reference, respectively the international, national, field and microeconomic references.

Gelei (2003) has used the definition of company competitiveness as „the basic capability of perceiving changes in both the external and internal environment and the capability of adapting to these changes in a way that the profit flow generated guarantees the long term operation of the company. As to him, company competitiveness is basically a function of two factors. First, it is determined by the extent a company can identify those value dimensions that are important for their customers. These are the main features of the companies' complex product and service package a customer expects. The second factor of company competitiveness is the sum of resources and capabilities that make a company capable to create and deliver the identified important value dimensions for the customer.

In the opinion of Asian Development Bank (2003), a company competitiveness can thus be examined as a function of factors such as: its own resources, its market power, its behavior toward rivals and other economic agents, its capability to adapt to changing circumstances, its capability to create new markets and the institutional environment, largely provided by the government, including physical infrastructure and the quality of government policies.

Different other authors have also tried to identify the determining factors of competitiveness at the company level, which they took into account in the elaborated analysis models. Thus, Schmuck (2008) builds a measurement index for the relative regional competitiveness of the companies in the South Trans-Danube Region, including in the model as variables: the workforce fluctuation as competitiveness destabilizing factor, the participation to alliances, the adaptation to changes and the alteration of the held market share. On his turn, Markus (2008) suggests a measurement possibility of the company competitiveness, starting from Porter's Diamond Model, identifying as influence variables of company competitiveness: the number of years since the company foundation, the financial perspectives, the lack of skilled experts, the cooperation with other organizations, the demand index, the trend of sale incomes and innovative activities.

We consider that the factors synthesized by Ternisien and Diguët (2001) for the company competitiveness assessment, respectively the dimension and intensity which it uses the sponsors' capital, the organizational capital, the human capital, the innovational capital and the capital represented by the customers portfolio, are relevant to analyze and explain the competitiveness advantage of a company in regard to another.

Thus, the company competitiveness is influenced by the diversification of the financing sources, by the sponsors' loyalty and availability to contribute to the support of development strategies, but also by the access to the less expensive financing resources.

The method of organizing the entry and exit flows together with the efficiency of the responsibility centres existing at the companies' level characterize the quality of the organizational capital. It can provide output increases and the value creation. The

autonomy of the responsibility centres which operate coordinately to achieve the pre-established competitiveness objectives provides the flexibilization of the decisional act. The flexibility of the organizational capital influence on the company capacity to react quickly to structural changes but also conjunctural changes arisen on the market.

The quality of the goods and services offered by companies is influenced by the level of training and social-cultural values characterizing the used human capital. It provides the competitiveness differential and is reflected in the performance increase in regard to the other competitor companies, contributing to the creation of added value and finally to the profit increase.

In order to respond to the change of the consumers' preferences and the predictable dynamics of the demand structure, the companies must develop and take advantage of the innovational capital they possess. The research – development activities are those which provide the existing technologies' improvement, the building of new technologies, the offer of new goods and services. But the existence of these activities depends on the capacity of attracting creative human capital and with spirit of initiative.

Capitalization of the market supply depends on the customer portfolio of the companies, on its loyalty but also the attraction of new customers. The competitive companies are those which manage to anticipate and respond to the customers' demand before others whom they compete on the market. Companies must attract customers with a good position on the market and to welcome their needs.

## **2.Empirical study regarding the determining factors of the Romanian companies competitiveness**

In order to identify and assess the factors determining the company competitiveness on the competitive market we have used the questionnaire method as method of research. The object of the applied questions was to test the managers' opinions regarding the factors determining the competitiveness of the companies they manage.

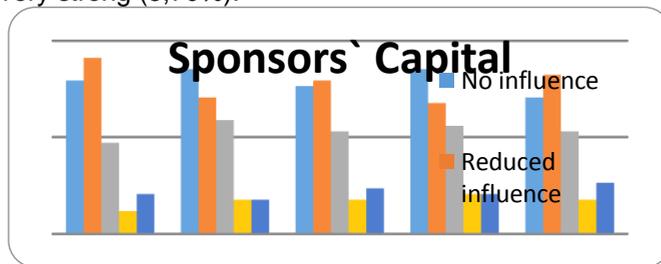

The competitiveness determining factors which made the object of the questionnaire explorative questions are synthesized by Ternisien and Diguet (2001) for the company competitiveness assessment, respectively the sponsors' capital, the organizational capital, the human capital, the innovation capital and the capital represented by the customer portfolio.

The assessment of the factors' impact on competitiveness was made based on the answers received from the respondent managers, by giving certain marks, such as: 1 = no influence; 3 = reduced influence; 5 = medium influence; 8 = strong influence; 10 = very strong influence. The time interval taken into consideration is 2008-2012. The initial sample of companies which we took into consideration consisted of a number of 300 Romanian companies. 127 managers answered to the applied questionnaires but because of the significant number of non-answers existing in their content, the sample was reduced to 85 companies which are part of 14 fields of activity provided in the NACE Rev. 2 classification.

The company classification on size classes took into account the following classification criteria: the number of employees, the annual net turnover and the value of the total assets held. Since for about 92% of the interrogated companies the cumulative criteria for the classification into a certain size class are not fulfilled, the single relevant criterion which could be held was the number of employees.

According to this criterion, the distribution of answers shows that from the total of 85 companies: 63 companies representing 72,12% of the sample are classified in the microenterprises' category, 14 companies representing 16,47% of the sample are classified in the small enterprises' category; 8 companies representing 9,41% of the sample are classified in the medium enterprises' category. The data was processed at the level of the entire sample and according to fields of activity, and the answers assessed through marks were transformed in relative sizes.

At the level of the entire sample, the influence of the sponsors' capital on competitiveness reflects an almost similar distribution of the respondents' opinions for the full analyzed period. The companies estimating that it has a reduced influence (31,29%) and no influence (29,94%) are preponderant. Only for an average of 21,41% of the companies, the influence of the sponsors' capital is a medium one and even more reduced is the number of those for which the influence is strong (6,83%) or even very strong (8,70%).

**Figure 1:** The influence of the sponsors' capital on the company competitiveness  
Source: data processed by the authors, according to the questionnaire

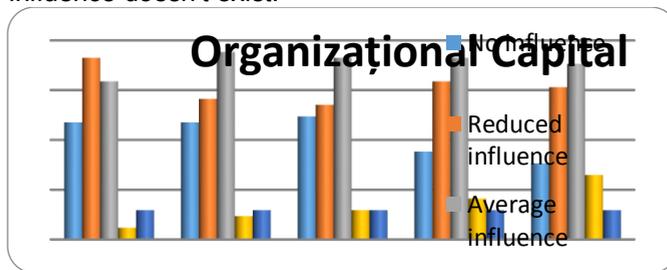

The analysis refinement at the level of the economy fields in which companies activate emphasizes differentiations between them regarding the influence exercised by the sponsors' capital on competitiveness. Thus, from the total companies activating in the *manufacturing industry* almost half of them (41,82%) confer to this factor a reduced influence while 29,09% estimate a medium influence. However, 18,18% of them consider that the influence is very strong and only 1,82% estimate that this factor exercises a strong influence, while 9,09% estimate that the sponsors' capital doesn't exercise any influence on their competitiveness.

Regarding the companies activating in *buildings*, almost half of them (43,33%) don't attach importance to the influence of sponsors' capital on competitiveness and a quarter of them (25%) attach a reduced importance. While 8,33% of the field sample estimate a very strong influence and 16,66% a strong importance, 6,68% of the companies estimate a medium influence.

The analysis of the answers received from the companies in field of *transport and storage* allows us to notice that for 23,64% of them the sponsors' capital has no influence on their competitiveness, for 40% of them it has a reduced influence and for 27,27% it has a medium influence. From the total companies of the sample, which activate in *wholesale trade or retail trade*, 27,36% estimate that sponsors' capital doesn't exercise any influence on their competitiveness, 34,73% estimate that it has a reduced influence and 24,22% a medium influence. Only 6,32% of the companies estimate the sponsors' capital as being a factor with a strong influence on competitiveness, while 7,37% of them confer a very strong influence to this factor.

We can notice a similar behaviour of the majority of companies developing *activities of administrative services and activities of support services, shows, cultural and recreational activities*, as well as those in the fields of *information and communications, real estate transactions and education*, these estimating that sponsors' capital doesn't exercise any influence on their competitiveness. As opposed to them, the dominant value of the companies developing *professional, scientific or technical activities, as well as the financial brokerage activities*, confer a reduced influence to this factor. The majority of the companies activating in the field of *health and social welfare*, as well as in the field of *production and supply of electricity and thermal energy, gas, hot water and conditioned air* estimate the sponsors' capital as being a factor with a medium influence on competitiveness while the majority of the companies in the field of *hotels and restaurants* confer a strong influence to this factor.

At the level of the entire sample, the influence of the *organizational capital* on competitiveness reflects a similar distribution in the first and the last two analyzed years, in comparison with the second and third year. Only 5,88% of the companies consider that the influence is very strong and 6,82% estimate that influence is strong. We notice the prevalence of the answers attaching a medium importance of 35,29%, followed by those for which, with an average of 30,82%, the influence is reduced and for 20,93% the influence doesn't exist.

**Figure 2:** The influence of the organizational capital on the company competitiveness

Source: data processed by the authors, according to the questionnaire

Analyzing this influence at the field level, we notice that in the *manufacturing industry*, more than a half of the companies (56,36%) confer a reduced influence to this factor and a quarter of them (25,46%) a medium influence.

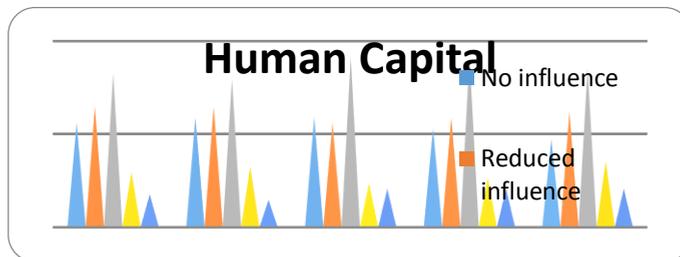

If the analysis reference is represented by the companies which activate in *buildings*, the majority of them (36,66%) doesn't attach importance to the influence of organizational capital on their competitiveness, and a quarter (25%) attach a medium importance. The companies attaching a reduced influence of the organizational capital on the competitiveness or confer a very strong influence to this factor, have equal values (16,67%).

The analysis of the answers received from the companies in field of *transport and storage* allows us to notice that for 25,46 % of them the organizational capital has no influence on their competitiveness, for 29,09% of them it has a reduced influence and for 36,36 % it has a medium influence. From the total companies activating in *wholesale trade or retail trade*, 18,95% estimate that organizational capital doesn't

exercise any influence on their competitiveness, the companies estimating in equal values (37,89%) either a reduced or a medium influence of this factor.

Regarding the majority of companies developing *activities of administrative services and activities of support services, professional, scientific or technical activities*, as well as those in the field of *hotels and restaurants, information and communications, the production and supply of electricity and thermal energy, gas, hot water and conditioned air, health and social welfare*, we can notice a similar behaviour, these attaching a medium importance to the influence of the organizational capital on competitiveness.

At the level of the entire sample, the influence of the *human capital* on competitiveness reflects an almost similar distribution of the respondents' opinions for the entire analyzed period. The companies estimating that it has a medium influence dominate with an average of 34,35%, followed with an average of 24,46% by those considering that the influence is reduced, while 21,87% consider that there is no influence. Only 11,77% of the respondents consider that the influence of the human capital on competitiveness is strong and even smaller is the number of those for which influence is very strong (7,53%).

**Figure 3:** The influence of the human capital on the company competitiveness  
Source: data processed by the authors, according to the questionnaire

At the field level, we observe the existence of certain differences regarding the influence exercised by the human capital on the company competitiveness. Thus, in the *manufacturing industry*, 41,82% of the companies confer a reduced influence to this factor, 30,90% of them confer a medium influence and 14,55% consider that there is a very strong influence.

The analysis of the companies in the field of *buildings* allows us to notice that for 30% of them the human capital has no influence on their competitiveness, for 11,66% of them it has a reduced influence and for 23,34% it has a medium influence. Relatively similar values hold companies attaching a strong importance to the influence of human capital on competitiveness (18,33%) or they confer a very strong influence to this factor (16,67%).

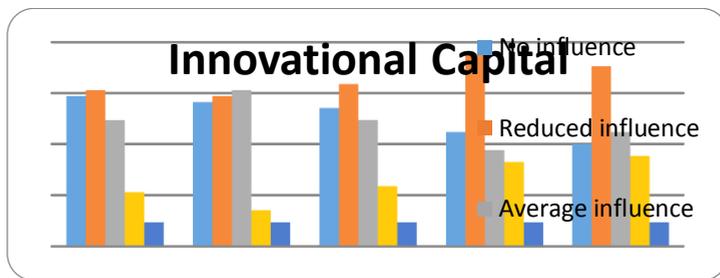

Regarding the companies activating in the field of *transport and storage*, almost half of them (40 %) attach a medium importance to the influence of human capital on their competitiveness, 21,82% of them attach a reduced importance and 27,77% of them don't attach any importance. For 10,91% of the companies the influence of the human capital is strong and at the field level there's no company in whose opinion the influence is very strong.

From the total companies of the sample which activate in *wholesale trade or retail trade*, 17,89% of the companies estimate that the human capital doesn't exercise

any influence on their competitiveness, 33,68% of them confer a reduced influence to this factor and the majority (37,89%) a medium influence. The companies conferring to this factor a strong influence or even a very strong influence on their competitiveness, have equal values (5,27%).

The dominant value of the companies developing *shows, cultural and recreational activities, professional, scientific or technical activities* but also the companies in the fields of *information and communications, the production and supply of electricity and thermal energy, gas, hot water and conditioned air, health and social welfare*, attach a medium importance to the influence of the human capital on competitiveness.

At the level of the entire sample, the influence of the *innovational capital* on competitiveness reflects a different distribution of the respondents' opinions in the first two years in comparison with the last two years of the analyzed period. With an average of 32,94% the estimation of a reduced influence is predominant and it is followed by an average of 25,41% referring to the lack of a influence on competitiveness. For 24,23% of the companies the influence of innovational capital is a medium one and even more reduced being the number of those for which the influence is strong (12,70%) or even very strong (4,70%).

**Figure 4:** The influence of the innovational capital on the company competitiveness  
Source: data processed by the authors, according to the questionnaire

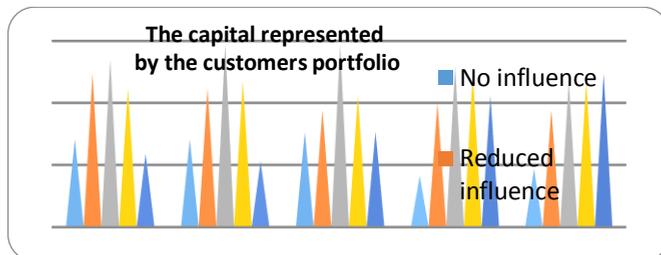

The analysis refinement at the level of the fields emphasizes differentiations between them. In the *manufacturing industry* almost three quarters of the companies (74,55%) confer to this factor a reduced influence and 10,90% of them estimate that this factor has no relevance for their competitiveness. For 3,65% of the companies the influence of the innovational capital is a medium one and even more reduced is the number of those for which the influence is strong (1,81%). The analysis of the companies in the field of *buildings* allows us to notice that for 38,33% of them the innovational capital has no influence on their competitiveness, for 5% of them it has a reduced influence and for 13,33% it has a medium influence. In this field, 26,67% of the companies estimate a strong influence of this factor on their competitiveness and 16,67% of them estimate it has a very strong influence.

From the total companies activating in the field of *transport and storage*, 29,09% of them estimate that the innovational capital doesn't exercise any influence on their competitiveness, and the majority (38.18%) consider there is a reduced influence of this factor. In equal values (16,36%) the companies estimate either a medium influence or a strong influence. None of these companies activating in this field estimates that this factor exercises a very strong influence on competitiveness.

Regarding the sample companies which activate in the *wholesale trade or retail trade*, 25,26% of them estimate that the innovational capital doesn't exercise any influence on their competitiveness, the majority (34,74%) confer a reduced influence to this factor and 32,63% a medium influence. The companies conferring to this factor a strong influence (2,10%) or even a very strong influence (5,27%) on their competitiveness, have lower values.

Regarding the majority of the companies which develop *activities of administrative services and activities of support services, professional, scientific or technical activities*, as well as those belonging to the fields of *hotels and restaurants, information and communications, production and supply of electricity and thermal energy, gas, hot water and conditioned air*, we can notice a similar behaviour, these attaching a medium importance to the influence of innovational capital on competitiveness. The dominant value of the companies developing *shows, cultural and recreational activities* or activities in the fields of *education, real estate transactions, health and social welfare* estimates that their competitiveness is not affected by the innovational capital, while most of the companies in the field of the *financial brokerage* consider that the innovational capital exercises a reduced influence on their competitiveness.

At the level of the entire sample, the influence of *the capital represented by the customers portfolio* on competitiveness reflects an almost similar distribution of the respondents' opinions for the full analyzed period. We notice the prevalence of the companies attaching a medium influence of this factor (with an average of 27,05%) followed by those for which the influence of this factor is strong (with an average of 22,82%) and then, by those for which the influence is reduced (with an average of 20,94%). Only for 12,23% of the total sample companies, the capital represented by the customers portfolio doesn't exercise any influence on their competitiveness, while for an average of 16,70% of them the influence of this factor is very strong.

**Figure 5:** The influence of the capital represented by the customers portfolio on the company competitiveness

Source: data processed by the authors, according to the questionnaire

The analysis at the field level emphasizes the existing differences concerning the influence exercised by the capital which is represented by the customers portfolio on the company competitiveness. Therefore, in the *manufacturing industry* there haven't been identified any companies estimating that this factor has no influence on their competitiveness. Most of the companies in this field (38,18%) confer a reduced influence to this factor and about a quarter of them (25,46%) confer a strong influence. In equal proportions (18,18%) the companies in the manufacturing

industry estimate either a medium influence or a very strong one for the capital represented by the customers portfolio on their competitiveness.

The analysis of the companies in the field of *buildings* allows us to notice that for 25% of them the capital represented by the customers portfolio has no influence on their competitiveness, the same value having as well those attaching a strong importance to the influence of this factor, The companies of this field which estimate a very strong influence of the capital represented by the customers portfolio on competitiveness represent 23,34%.

From the total companies activating in the field of *transport and storage*, 18,18% estimate that the capital represented by the customers portfolio doesn't exercise any influence on their competitiveness, 23,66% consider that it has a reduced influence and the majority (32,71%) estimate that this factor has a medium influence. None of the companies activating in this field estimates that this factor exercises a very strong influence on competitiveness.

Regarding the sample companies which activate in the *wholesale trade or retail trade*, 6,32% of them estimate that the capital represented by the customers portfolio doesn't exercise any influence on their competitiveness, 26,32% of them confer a reduced influence to this factor and the majority (33,68%) a medium influence. The companies conferring to this factor a strong or even very strong influence on their competitiveness, have equal values (16,84%).

We can notice a similar behaviour of the majority of companies developing *activities of administrative services and activities of support services, shows, cultural and recreational activities, or professional, scientific or technical activities*, these estimating that the capital represented by the customers portfolio exercises a strong influence on their competitiveness. Taking into consideration the relatively reduced number of the sample companies, we estimate that the results cannot be extrapolated / generalized but we consider that they are relevant as a tendency for the microenterprises, small and medium enterprises from certain analyzed economic fields, namely trade, buildings, manufacturing industry, transport and storage, where the samples of received answers are more significant quantitatively. We observe that most companies consider that the influence of the analyzed factors on competitiveness is medium and respectively reduced, while a small number of questioned factors estimate that these exercise a strong and very strong influence. Among the analyzed factors, the organizational, human capital and the customers portfolio are considered by the respondents, in a more significant extent, to influence the market competitiveness of the managed companies. The estimation concerning the lack of the sponsors' capital influence is surprising because without it neither the company existence and obviously nor the enforcement of certain policies in order to encourage competitiveness are possible. Such an answer determines us to consider that there is a dangerous deficiency of professional competence at the managers' level.

### **3.Conclusions**

The structure analysis of the sample reflects the dominance of the microenterprises which are followed at a long distance by the small and medium enterprises. We consider that the managers of the small sized companies as well as those in the held sample are based on a predominantly intuitive management, dealing the administered businesses based on the spur of the moment inspiration, making decisions subjectively not starting from objective economic criteria. They are

concerned only with the management of the current problems. Since they aren't the beneficiaries of a managerial education, they don't possess the necessary competences to focus on the elaboration of certain strategies by which to provide competitiveness and performance on the long-term. The managers' competence influences on the designing, promotion and application of a strategic vision which is capable to provide the economic competitiveness and the financial performance of the companies. Practically, the human capital is the one which identifies and activates the others determining factors of competitiveness.

In conclusion, we estimate that the maintenance and consolidation of the company position on the market are influenced by the structure optimization of the capitals derived from external shareholders and sponsors, but also by the way in which these are targeted for the fulfillment of research – development activities which generate new technologies and products creating a big added value, the fulfillment of strategic, development and updating investments, but also by the training level of the employed human capital. As a matter of fact, the flexibility of adaptation to the changes appeared in the demand structure depends on the innovational act. On its turn, the market share depends in the first place on the degree in which the offer of goods and services corresponds to the customers' consume preferences, so on the offer diversification and adaptation capacity, and on the companies' reaction to the signals transmitted by the market.

# STUDY ON THE PLACE OF ROMANIA IN THE HEALTH SYSTEM OF THE EUROPEAN UNION

**Nisulescu Ileana, Pana Elena Cristina**

*Academy of Economic Studies Bucharest, Accounting and Management of Information*

**Abstract:** *This study aims to present the concept of public health and the place of Romania in the health system of the European Union. The concept of public health grew rapidly throughout the European Union from a strict approach to health conditions in a comprehensive approach to the health of the population, living standards and a more healthy life, even amid economic crisis that affected the whole of Europe.*

*Policy makers have made considerable efforts to ensure access to high quality medical assistance facing challenges rarely encountered in other parts of the world, such as aging population, the use of more effective drugs and some more advanced technology.*

*In order to position Romania in the EU context, we used a comparative analysis, using a number of indicators, such as total health expenditures in GDP and per capita, and life expectancy at birth, number of hospital beds and number of doctors/100,000. The result in most indicators showed that Romania is in an inferior position, except the indicator number of hospital beds. However, in this case we must take into account that we had data published by the World Bank in 2010, and the following year they abolished a total of 67 public sector hospitals.*

*These conclusions are all the more disappointing, because throughout Europe during the crisis was drastically reduced the budget spending on health, which affected both the public and private health. In this regard wages were reduced, they stopped hiring in the public sector, and healthcare staff migrated in search of higher incomes and better working conditions.*

*Successful experiences of the EU members countries have shown that some types of social policy and investment strategy in education in general and education for prevention and sanitary behavior in particular, lead to a long term positive impact on population health.*

**Keywords :** *health care, the budget, doctors, life expectancy, hospital beds.*

## 1. Introduction

Ensuring access to adequate health care is a fundamental policy objective in all Member States of the European Union, and in this respect, in the last 30 years, health system resources, experienced steady growth. Increasingly, there are concerns in many European countries about the lack of doctors and nurses, although recent cuts in public health expenditure in some countries at least temporarily reduced the demand.

By 2009, health spending in GDP in European countries grew at a faster pace than the growth rate of economic growth. Following the financial and economic crisis in 2008, several European countries were forced to cut health spending. This has had a devastating impact on the fundamental objectives of health systems- putting

additional pressure on many European countries health system. Public health spending cuts were made through a series of measures which included: reducing wages and / or employment levels, increasing direct payments made by the population for certain services and pharmaceuticals, and the imposition of hard budget constraints on hospitals. Also, mergers between hospitals were made by the officials by stopping the ones declared inefficient or by accelerating the change from inpatient care to outpatient care.

Starting from these considerations we attempt to make a comparative study of EU countries and Romania, considering a selection of new indicators considered relevant to characterize the health system of a country.

## **2. State of knowledge**

"Health is a characteristic of an inalienable good and it resembles in a small extent with other forms of human capital such as education, professional skills and sports performance. It is subject to important and unpredictable risks which confirm that health is entirely different from all other goods that people insured against theft or hazard and that is why sickness insurance is more complex than any other type of insurance." (Constantin and Ganescu. 2009:51)

"Having good health is an essential element to quality of life, element indicated by people" (Delhey 2004:6). Bogdan Voicu (2005:27) and Cosmina Elena Pop (2010:7) consider human capital as consisting of two components: "educational capital (skills acquired by individuals in training school but also outside it) and biological capital (physical abilities of individuals, synthesized, most often in health). "After joining the EU, the state of population health and health services in other Member States has become a reference point for our country. Health reforms are initiated by three major factors: poor health of the population, dissatisfaction of actors in the system and reduced performance of the system, as shown in international statistics." (Vlădescu, Astărăstoae and Scintee 2010:8)

In view of better determining the health state "Indicators meet the need for deeper understanding of phenomena and interrelations between them, which otherwise escapes understanding. They sum and associate data of monitoring and surveillance systems so that they can provide answers to questions relevant to the planning and management of health problems." (Dragoi 2008:3) Among these indicators, a priority is given to lifespan. This "rose in the EU, so did the share of the aged population (the main consumer of services in the total population).

All these fiscal pressures make the developed countries to provide new sources of financing, the most efficient management of existing resources or alternative ways of organizing services (a mix of private and public) (Cristina Tomescu 2009:5).

Another indicator for the health state is the number of physicians and the distribution thereof. In most countries, the number of specialists is higher than the generalists "This can be explained by a lower interest in the traditional practice of generalist medicine (family doctors), given the workload and the constraints attached to it. In addition, in many countries, the pay gap between generalists and specialists is quite high (Fujisawa and Lafortune 2008:27). "

"Migration of Romanian doctors is a current component of the more general phenomenon of labor migration from Romania having relevant socio-economic effects on public health. The level of remuneration of medical personnel in Romania can be considered a "push" factor of migration, valid not only for physicians but also for other medical staff.

Job satisfaction of physicians, in terms of income earned, is dependent on the level of economic development of the country” (Dornescu and Manea, 2013:134). In conclusion, Phillips (2006:16) believes that "a society can be differentiated by another in terms of quality of life in that society if people live longer, healthier and fullest life than in another community."

### **3. Research Methodology**

This paper combines qualitative and quantitative research, using specific methods, document analysis and content analysis. To achieve the objectives we used a series of bibliographical sources which consist of books, accounting rules, tax and legal studies and articles published in various national and international organizations in the field. Thus, we collected data from the World Bank, the National Institute of Statistics and Eurostat in order to make a comparative analysis, focus group type, in terms of health care, the EU-Romania, in 2010.

Thus, we used these variables, considered by us to be illustrative of a state health system dynamics:

- total health-spending in GDP
- Health expenditures per capita
- Life expectancy at birth
- number of hospital beds per 100,000 inhabitants
- number of doctors per 100,000 inhabitants

### **4 Results of data analysis**

System by which funds are generated and allocated in European health care system is very complex and varies from country to country. In most EU countries it is used a system consisting of government funding of health and social security contributions, resources continuously increasing in most Member States in the last 3 decades.

Some of the most important factors behind this growth were aging of population, increasing the number of persons receiving medical assistance, and the discovery of more effective drugs and advanced technologies.

In this respect, we prepared a table of health system indicators with data recorded in the year 2010.

#### ***Table 1. Indicators of the health system***

Country	Health expenditure in PIB (%)	Life expectancy (years)			No of hospital beds for 100.000 inhabitants	No of doctors for 100.000 inhabitants
		Women	Men	Average		
UE-27	10,3	82,9	77	79,95	538,2	340
Belgium	10,5	83	77,6	80,3	644	292
Bulgaria	7,2*	77,4	70,3	73,85	661,6*	371,1
Rep. Czech	7,5	80,9	74,5	77,7	701	358
Denmark	11,1	81,4	77,2	79,3	349,8	350
Germany	11,6	83	78	80,5	824,8	373,1
Estonia	6,3	80,8	70,6	75,7	533,1	323,5
Ireland	9,2	83,2	78,7	80,95	313,9	310
Greece	10,2	82,8	78,4	80,6	484,8*	610
Spain	9,6	85,3	79,1	82,2	315,7	377,9
France	11,6	85,3	78,2	81,75	642,4	330
Italy	9,3	85	79,8	82,4	352,5	370
Cyprus	7,4	83,9	79,2	81,55	368	310,7

Sweden	9,6	83,6	79,6	81,6	272,6	380
Unit. Kingdom	9,6	82,6	78,7	80,65	295,5	271,2

\* 2010 data were not available we used 2009 data  
 Provided by authors, source Eurostat, World Bank

### Total expenditure on health

These include the provision of health services (preventive and curative) and emergency medical aid, family planning, nutrition.

Health insurance contributions are made on their income and their pay is split between employer and employee, there are still relevant differences between EU countries in terms of uniformity and variability of rate, distribution between employer and employee, the existence of an upper limit to the contribution existence of other types of contributions outside of the salary. In countries like Germany, Austria, Holland contributions have upper limits.

In France, in order to develop the base of funding, the amount for the employee was replaced by a general social contribution which is not based on wages. In most EU countries, the distribution between employee and employer is in favor of the employees, employers paying between 70-90% of the contribution. However, in countries like Romania, Austria and Belgium, the distribution of employee / employer is almost equal. Private insurance system is a health supplement that provides additional coverage for services not covered partially or fully by the social ones. Percentage of GDP (Table 1) allocated to Health recorded variations from country to country. Calculated as a percentage of GDP, total health expenditure is, in Romania, 6%, the lowest percentage allocated to the health of the countries with available data. Within the EU, health spending varies from 7.2% in Bulgaria and 12% Netherlands.

Romania has allocated total health expenditure in the period 2005-2010, 44% lower than the EU average, but the situation is even more critical in terms of actual

expenditure on health per capita, which stood at a value of 19.56% compared to the EU. Analyzing this indicator it was observed that Romania spends the lowest amount per capita in EU countries.

### **Life expectancy at birth**

Indicator of the health of the population, "opposite" of mortality, life expectancy targets the average life of an individual

Life expectancy at birth, also called disability-free life expectancy is an indicator that reflects the state of good health, combining information on mortality and morbidity in the population. It shows the number of years that a newborn can live them, respecting the same lifestyle up to death. . It (Table 1) increased in the EU, so did the share of aging population in the total of population. Along the Baltic countries, Bulgaria and Romania are among the countries with the lowest life expectancy among EU countries.

Romania with a hope of only 77.6 years for women and 70.1 years in men is on the last place in the EU, compared to the EU average 79.95 years. Women in Romania live 8.2 years less than those in France, considered the oldest women in Europe. At the level of the entire population, in Spain, France and Italy the hope is noticeably higher than the EU average. Although the general trend is increasing, in 2010, life expectancy in the EU has decreased compared to 2009, due, undeniably to global economic crisis. Inequalities between women and men in terms of life expectancy at birth are very different across countries, being more pronounced in the Baltic countries (over 10 years) and in South-Eastern and Central Europe (between 6-9 years).

### **Number of hospital beds per 100,000 inhabitants**

Number of hospital beds (Table 1) is an indicator affected by the state of health of the population, the average days of hospitalization, rate of hospitalization, treatment complexity, technical resources and outpatient treatment.

Romania has the highest rate of hospitalization in the EU, 215.13 admissions per thousand inhabitants, while the Netherlands recorded the lowest rate of hospitalization, with 109.3, followed by England - with 128.7, and France - 171.5.

In 2010, the EU, the average number of beds was 538.2, with 101.9 fewer than in 2000. This indicator varies from state to state, from 272.6 in Sweden, to 824.8 in Germany. In the period 2000 - 2010 the number of hospital beds has decreased, in each Member State, except Greece. The largest decreases were registered in Ireland, Finland, France, Slovakia and Romania. These reductions may reflect, among other things, economic constraints, increasing efficiency through the use of technical resources (e.g. imaging equipment), and a general shift from inpatient to outpatient operations and shorter periods in hospital after an operation.

In Romania in 2011, as a result of structural changes in the health care system, by stopping funding for a total of 67 hospitals in the public sector, the number of beds decreased with 3503. The public and private units for 2012 were approved with less than 2862 beds in 2011, although five hospitals were reopened. This is due to rehiring specialist doctors, complexity of medical services offered, addressing, trying accessible hospital services for the insured and balanced functioning of all hospitals.

### **Number of physicians per 100,000 inhabitants**

Many EU countries are concerned with the lack of current and future physicians, especially some doctors in respective categories. In almost all EU countries, the balance between general practitioners and medical specialists changed, increasing the number of specialists.

Slow or negative growth in the number of general practitioners raised concerns in the European Union countries in access to primary care for the population.

In 2010, Greece had by far the highest number of doctors per capita, 610, almost twice the EU average of 340 (Table 1). Number of doctors was also relatively high in Austria, Norway, Portugal, Sweden, and Spain. The lowest number of doctors is found in Slovenia, followed by Romania and Poland.

The problem of Romanian doctors' migration is that some doctors are renowned specialists and prestigious academics and their departure means the loss of super-qualified professionals and mentors of future generations of physicians.

The level of remuneration of medical personnel in Romania can be considered a "push" factor of migration, valid not only for physicians but also for other medical staff. Job satisfaction of physicians in terms of income earned is dependent on the economic development of the country and can be determined by comparing individual physicians' gross income to average wages in total economy. Level - already very low - of the remuneration of medical personnel was affected by the economic crisis austerity measures taken by the Government.

## 5. Conclusion

Health is an area of major social impact, which may provide evidence for the adoption of policies, it representing fundamental value both for individuals and for society. The health system has been for a long time in a state of prolonged crisis and public health issues and challenges of the Romanian medical system are long-term problems whose consequences will be felt in the future.

Low living standard of the population and lower health system resources are the prime causes of health of the population of Romania. Although, in the period 2003-2010, Romania grew significantly by 140.6% total health expenditure per capita, though we are in last place in Europe in the year 2010 with only 353.4 euro / capita, being surpassed by all members of the communist camp about 2-3 times. The economic crisis that hit the entire European Union, health spending in some countries was reduced by cutting public spending (France, Sweden, Finland, Germany). Reducing salaries, stopping hiring in budget inflexibility, unemployment are just a few factors that affected population and standard of living leaving its mark on both public health system, and especially private, throughout Europe.

Both objective indicators and subjective ones place Romania among the EU countries with poor health status. The data indicate health as a key area requiring intervention by social policies and the lack of an effective investment in reducing urban-rural disparities in the provision of public services and reduced financial involvement in initiating effective programs for public health / prevention are important points that emphasize differences.

Financial disparities between the rich and poor investment explains deficiencies in poor areas. There was no effective policy to attract, by financial incentives serious medical personnel in rural areas.

Improving the health system in Romania is related to the economic development of the country, and therefore a long-term problem. In this context, we must consider a range of policies to target by high financial involvement the main weaknesses of health in Romania: better care of mother and newborn, investing in children and in education for prevention, primary care in rural area.

All these measures will impact life expectancy (73.85 years) and therefore the proximity to the European average (79.95), knowing that for this indicator we stand

in last place in Europe. First on the list of causes of death in Europe is due to cardiovascular disease (heart attack and stroke), followed by oncologic diseases, suicides and traffic accidents.

Economic development is another important factor that led over the past six decades to a dramatic increase in life expectancy and quality of life in developed countries.

Developments in medical equipment and drugs, healthy eating, providing sanitation, public information on prevention / treatment, were also an important factor that helped this growth. Women live longer mainly because they are more attentive to symptoms and go to the doctor more often, counting more on prevention and are less involved in highly dangerous work.

In the period 2007-2012, in Romania there have left to work in other countries 12,214 physicians and specialty exam was passed only by 6,200 aspirants. Therefore, in Belgium, of all the doctors entering the workforce each year, one in eight is Romanian. This is due to several factors, such as higher wage, working conditions, technical equipment.

Resource allocation in the system should be redesigned in the sense of investing more in rural primary care. Also other dimensions of the system should be reconsidered in order to increase quality of care and public access to it. In this sense, the destruction of hospitals in 2011, has reduced the number of beds, where Romania was ranked 10th in Europe, well above the EU average and hence the number of physicians, where Romania is a disgraceful place 26. The measure, potentially beneficial in the global level, but only erratically enforced deepen the crisis in the system, a large number of doctors and nurses migrating to other countries where the income is over 3 times higher and working conditions are better.

Economic development will solve many of the problems that Romania is facing, bringing improved health and quality of health services offered. Successful experiences of countries member EU have demonstrated that some types of social policy as well as a strategy for investment in education in general and education for prevention in particular, lead to long-term positive impact on population health.

# ESTIMATING QALYS IN THE WESTERN REGION OF ROMANIA – THE CASE WITH INTERVENTION

**Pantea Marius, Gligor Delia**

*Management Department, Faculty of Economics and Business Administration, West University of Timisoara, Timisoara, Romania*

[marius.pantea@feaa.uvt.com](mailto:marius.pantea@feaa.uvt.com)

[delia.gligor@feaa.uvt.com](mailto:delia.gligor@feaa.uvt.com)

**Abstract:** *Currently, we are in the process of experimenting a diversification and refinement of the consumer's expectations, as well as a growing demand for innovative, quality products and customized services, exacerbated by rapid technological change affecting both them and the producers. It is also the case of health services that, with Romania's accession to the EU, must align to the European requirements. In the context of limited public resources and growing healthcare needs, socio-economic criteria are necessary for substantiating allocation decisions. With the continuous increase in costs of medical interventions but also the expansion of the range of treatment options available, there is a need to develop and use a range of tools to help establish treatment adopted in the context of justifying the benefits resulting from its implementation. In health, the greatest difficulty for the documentation of investment projects is the main overall effect measurement and evaluation - improving quality of life. Although treated in the literature in terms of specialized clinical trials, there is not currently a methodology to address the economic evaluation of investment projects in health. In this sense, our study's objective is to develop and test a framework to estimate the most appropriate indicator that assesses improvements in quality of life due to healthcare investment projects. We have started with an extensive literature review that allowed us to identify the most recommended indicator in this sense - quality adjusted life years (QALYs) and also to develop and test a conceptual framework. We then realized a survey on 131 medical professionals from the Western Region of Romania, for the two main medical causes of decease, and based on the information collected we calculated the QALYs following a medical intervention. The values obtained reflect the impact of healthcare interventions in terms of quality of life improvements and have a high informational content being useful for those involved in policy making and building institutional capacity in terms of public resources allocation.*

**Keywords:** *cost-benefit analysis, economic analysis, public healthcare, quality adjusted life year, quality of life.*

**JEL classification:** *D61, H43, I15, I18, I31, J17, O22.*

## 1. Introduction

The addressed issues arise from the current situational context in terms of funding needs of the national public service sectors (especially health sector) due to limited public resources and allocation decisions in the absence of clear and socio – economic grounded criteria.

Romania's accession to the European Union (EU) in 2007 has rendered health and health services offered to the member states of the EU to become a frame of reference for Romanian citizens. Currently, the Romanian health system responds

inefficiently to the major health problems of the population, the financing of the health system being characterized by an inefficient use of resources.

A key issue in addition to underfunding is the arbitrary use of resources, the inequitable allocation between different regions, types of health services and even between different health institutions. Since new treatments and interventions are rarely more effective and less expensive than previous approaches, developing tools to guide decision making on health resource allocation process has become imperative in this regard.

In the context of healthcare valuation, specific methodologies have been developed, the most appropriate being the cost - benefit analysis (CBA). Cost-benefit analysis method is seen in the literature as a method of economic evaluation of social impacts of investment projects (especially those in the public domain) in areas such as health, education, environment, industry, transport, tourism and agriculture. In health, the greatest difficulty for the documentation of investment projects is the main overall effect measurement and evaluation - improving quality of life. Although treated in the literature in terms of specialized clinical trials, there is not currently a methodology to address the economic evaluation of investment projects in health. In this sense, our study's objective is to develop and test a framework to estimate the most appropriate indicator that assesses improvements in quality of life due to healthcare investment projects.

In order to fulfill the paper's objective, we have started with an extensive literature review, approaching the topics of healthcare economics, cost benefit analysis and quality of life and their study in the specific literature which allowed us to develop and test a conceptual framework.

Even though the originality of our research does not rely on the method applied (questionnaire survey), our results and conclusions have a high informational content and can be useful for those involved in policy making and public resource allocation decision makers.

## **2. Literature review. Theoretical framework**

The scientific concerns on the issue of cost-benefit analysis and its implications on the decision to fund a social project with environmental impact can be found in the literature since the early nineteenth century, yet it still is the subject of a continuous research due to uncertainties and difficulties identified in the background of the methodology especially in the case of healthcare interventions.

Thus, the research's starting point is health economics, a field of economics that studies what health is and what is its value (Evans and Lipp, 2009).

Recent research in health economics are focused on studying the opportunity of the state's intervention in the health sector by (Shiell et al., 2002, Buxton et al., 2004, Cyril and Nason, 2009):

- Ensuring the volume of medical services for which the effectiveness is demonstrated by clinical records and by improving the health safety of patients (micro-level perspective);
- Ensuring the volume of medical services at the lowest cost per unit of effect, recognized as effective in terms of technical equipment and in terms of the existence of medical staff;

- Providing resources according to actual healthcare needs, leading to the realization of the best value in health insurance by allocating those resources on the basis of effectiveness and medical priority.

Research interest in the health economy soared despite previous theories that the health resources should not be limited because in the future available resources will be sufficient to meet health care needs (Fuchs, 1986). This guidance is based on public resource allocation issues as public bodies are operating in both restrictive constraints of public resources and what is socially acceptable and economically feasible.

From this point of view, the cost - benefit analysis method provides information to substantiate the allocation of resources in order to maximize the health of the population (Borghi, 2008).

Recently, the research efforts have focused on this area, being driven by the possibility for public bodies to access national European structural funds to develop public services, being as such imposed the development of cost-benefit analysis (whose binding is derived from official documentation required in this case) starting from a well-established theoretical basis.

The need for health economic evaluation is outlined also by economic consequences of poor health status since health contributes to social welfare as follows: individuals prefer health status as high (thus health directly affects utility); consumption of goods and services is partly influenced by health (corresponding marginal utility of consumption is partly a function of health status); in lack of a high health status, other economic objectives - such as revenue growth to ensure access to goods and market services - may be compromised.

These observations underline the ways in which health problems can influence in a negative manner choices and preferences of households, businesses and governments aiming to maximize welfare.

In the public sector, and thus public health sector, cost-benefit analysis aims to appreciate the impact of governmental activity on the welfare of society in general and individuals and groups, in particular, taking into account ethics and efficiency issues in evaluating any project (Robinson, 1993).

In the public sector, public choice is oriented towards the interests of the majority and thus it affects the economic efficiency of human activity. In order to improve the economic performance of a society, public interventions are required.

But often these actions can cause negative socio - economic effects, suggesting the need to substantiation decision making process by undertaking a cost - benefit analysis.

The interest of the research results from the large number of papers published in the literature and from the international organizations' surveys that propose the determination of the impact a cost-benefit analysis has on the decision to implement a project regardless of the target (either public or private).

Thereby, from the relevant international and national studies, we have identified a set of guidelines and recommendations for developing CBA which although contain sector-specific elements required to be applied, follow the same methodology regardless of the issuing body (table 1).

**Table 1: Guidelines for CBA**

For healthcare interventions, currently there is no common understanding regarding the evaluation of the most important impact or benefit of these projects – citizens' quality of life. Measuring quality of life and survival not only allows on the one hand that patients, physicians and policy makers choose between curative intent treatment options without mitigating side effects or alleviating symptoms without healing surplus worth in life expectancy, and on the other hand, to choose between two treatments with similar survival benefits but with different side effects.

However, numerous studies and researches identify as a quality of life measurement indicator – quality adjusted life years (QALYs).

Defined as a summary measure of health outcome for economic evaluation, which incorporates the impact on both the quantity and quality of life (Whitehead and Shehzad, 2010), the concept was first used by Zeckhauser and Shepard (1976) in the context of public policy evaluation topics and developed by Klarman et al. (1968) through an assessment of the effectiveness of dialysis study. It was Pliskin et al. (1980) that defined the term in the sense discussed today, therefore helping to demonstrate the usefulness of a medical intervention.

The paper's goal is therefore to propose a methodology to estimate the quality of life indicator identified – quality adjusted life year (QALY).

### 3. Research methodology

#### 3.1. Research problem and hypothesis

The use of QALY in the economic analysis of health investment projects suppose an answer to the following research question: What is the number of QALYs gained for each medical specialty through health interventions?

It should be noted that there is no common opinion in the national but especially international research on this topic regarding such an approach, we only identified disparate estimates for QALY for specific medical conditions (for example Miller et al., 2009).

Since determining the QALYs gained through health interventions necessitates a

prior determination of the number of QALYs when no intervention is considered and the QALYs with intervention, in this paper we concentrated our efforts in identifying the number of QALYs when interventions are considered. Our prior research in this field aimed at determining the number of QALYs in the case without intervention (Pantea and Gligor, 2012a). As such, the research hypothesis is the following: The number of QALYs with intervention is higher than the number of QALYs without intervention.

### **3.2 Survey design**

Our following concern was to identify the research method that enables testing and validating the assumptions in the context of the paper's objectives. Thus, following an analysis of the methods indicated by the literature review, we conducted a quantitative research, the instrument used for data collection being the questionnaire.

As stated by Pantea and Gligor (2012b), to estimate the number of QALYs for a group or a population the following types of information are needed:

- Descriptions of the various types of perceived health status in life;
- The duration of each health state;
- Estimation of utilities for each state for a group or an analyzed population.

With regards to the medical conditions that we included in our research, we started with an analysis of the statistical information provided by the Newsletter No. 11 of 2011 of the National Center for Public Health Statistics and Informatics which sets out the causes of death by age and gender of the population. Thus, we selected for this research only the first two main causes of death in Romania – diseases of the circulatory apparatus (60% of total deaths) and tumors (20% of total deaths), the selection criterion being the disease with the highest percentage in total deaths.

A second point of interest was to determine a common scale for both medical conditions in terms of evolutionary stages since each condition's stage is different in features and pathology. The objective was to create a common framework that allows comparisons between medical specialties, which we developed as follows (Pantea and Gligor, 2012b):

- Stage 1 - the initial stage: the first signs of disease onset, when medical interventions are often completely noninvasive and determine a complete recovery;
- Stage 2 - the advanced stage: requires invasive interventions which sometimes cause a partial or complete treatment of the disease;
- Stage 3 - final stage: reserved prediction, reduced ability to use medical interventions.

Based on the informational needs, we have developed the investigating tool necessary to achieve the established objectives that ensures the collecting of all the mentioned data.

Thereby, we developed a questionnaire that approaches two informational needs: on the one hand, respondents' perception regarding patients' quality of life after medical intervention and the identification of the associated quality of life utility in the three stages of the two diseases analyzed.

The target population consists of medical professionals since they are the only ones able to assess from a medical standpoint and in an objective manner the patients' quality of life after medical interventions. Restrictions of high amplitude and resource consumption in analyzing the total target population, led to a smaller sample population represented by healthcare professionals working in major hospitals in

the Western region of the country.

In table 2 we illustrated the process of operational definition of the questionnaire's variables.

**Table 2: Operational definition of variables**

Questionnaire theme		Variable	Variable operational definition
Perception of patients' quality of life after medical interventions	Diseases of the circulatory apparatus – Stage 1	Health state utility	0 – Worst health state 1 – Best health state
	Diseases of the circulatory apparatus – Stage 2	Health state utility	0 – Worst health state 1 – Best health state
	Diseases of the circulatory apparatus – Stage 3	Health state utility	0 – Worst health state 1 – Best health state
	Tumors – Stage 1	Health state utility	0 – Worst health state 1 – Best health state
	Tumors – Stage 2	Health state utility	0 – Worst health state 1 – Best health state
	Tumors – Stage 3	Health state utility	0 – Worst health state 1 – Best health state
Respondent's profile		Profession	Medical doctor
			Resident physician
			MD
			Medical specialist

In order to demonstrate the reliability of the measurement scales, we calculated the  $\alpha$  Cronbach coefficient and obtained an average of 0.77. Since sociological surveys consider satisfactory a value higher than 0.7, we demonstrated the reliability of the proposed scales.

On the basis of information on the utility associated with quality of life after surgery and considering time as life expectancy in Romania (values for 2011), we can calculate QALY for the case with intervention using formula 1.

$$\text{QALY with intervention} = \sum_{t=a}^{a+L} Q_t^i \quad (1)$$

where,

t – time period;

a – age;

$L^i$  - the period over which the individual enjoys the benefits of treatment;

$Q_t^i$  - a vector of health-related quality of life weights predicted (or observed) for each time period  $t$  following the intervention.

#### 4. Data analysis and results

The process of data collection was realized by direct research, which allowed us to eliminate the risks related to invalid questionnaires and to ensure the defined sample volume. The data was collected from January to February 2013 and processed using SPSS 17. Out of 150 questionnaires delivered to 10 major medical units from the Western Region of Romania, we collected 131 valid questionnaires, thus a 87% response ratio.

The investigated population analysis according to the variable 'profession' reflects a following structure: 22% medical doctors, 23% resident physicians, 29% MDs and 26% medical specialists.

The starting point in processing the collected data was to establish their homogeneity level by calculating for each variable the central tendency indicators (mean, median, mode) and dispersion indicators (minimum, maximum amplitude, variance, standard deviation). The results obtained indicate a high homogeneity of data as amplitude, variance and standard deviation values are below one and close to 0. The fact that the values of mean, median and mode indicators are approximately equal underlines the symmetry in data distribution and justifies the use of their average values in determining the utility for each stage of the medical conditions considered.

Identification of time spent in each stage was based on the increase in life expectancy percentage due to medical interventions that each respondent identified according to specified criteria.

After calculating tendency and dispersion indicators, the results obtained allowed assessment of the increase in life expectancy percentage as average values observed.

The calculation of life after surgery, by age, followed the reasoning explained as follows:

Average life expectancy after diagnosis = Age × Average life expectancy at diagnosis

Years of life lost = Average life expectancy – Average life expectancy after diagnosis

Years of life gained = increase life expectancy % × Years of life lost

Average life expectancy after intervention = Average life expectancy at diagnosis + Years of life gained

The calculated values for average life expectancy after intervention, based on the above reasoning, reflect a significant difference between the average lifespan at diagnosis and life expectancy after surgery, both on stages of the disease and types of medical conditions.

In order to calculate quality adjusted life years with intervention, we applied formula 1 using quality of life related utility values ( $Q_i$ ) previously determined by statistical methods and average life expectancy values after intervention (DI) based on data collected and processed in the previous step (table 3).

**Table 3: QALYs with intervention**

Medical condition	Age group	Qi	Di	QALYs
<b>Stage 1</b>				
Diseases of the circulatory apparatus	under 24 years	0,9	46,23	<b>41,61</b>
	25 - 34 years		37,79	<b>34,01</b>
	35 - 44 years		29,31	<b>26,38</b>
	45 - 54 years		20,68	<b>18,61</b>
	55 - 64 years		11,98	<b>10,78</b>
	over 65 years		3,52	<b>3,17</b>
Tumors	under 24 years	0,71	31,41	<b>22,30</b>
	25 - 34 years		25,84	<b>18,35</b>
	35 - 44 years		20,25	<b>14,38</b>
	45 - 54 years		14,69	<b>10,43</b>
	55 - 64 years		8,78	<b>6,24</b>
	over 65 years		3,06	<b>2,17</b>
<b>Stage 2</b>				
Diseases of the circulatory apparatus	under 24 years	0,77	36,41	<b>28,04</b>
	25 - 34 years		29,84	<b>22,98</b>
	35 - 44 years		23,27	<b>17,92</b>
	45 - 54 years		16,30	<b>12,55</b>
	55 - 64 years		9,56	<b>7,36</b>
	over 65 years		2,95	<b>2,27</b>
Tumors	under 24 years	0,55	25,19	<b>13,85</b>
	25 - 34 years		20,55	<b>11,30</b>
	35 - 44 years		15,92	<b>8,75</b>
	45 - 54 years		11,36	<b>6,25</b>
	55 - 64 years		6,83	<b>3,76</b>
	over 65 years		2,31	<b>1,27</b>
<b>Stage 3</b>				
Diseases of the circulatory apparatus	under 24 years	0,57	29,01	<b>16,53</b>
	25 - 34 years		23,71	<b>13,51</b>
	35 - 44 years		18,41	<b>10,49</b>
	45 - 54 years		13,11	<b>7,47</b>
	55 - 64 years		7,81	<b>4,45</b>
	over 65 years		2,51	<b>1,43</b>
Tumors	under 24 years	0,43	17,38	<b>7,47</b>
	25 - 34 years		14,28	<b>6,14</b>
	35 - 44 years		11,18	<b>4,81</b>
	45 - 54 years		8,08	<b>3,47</b>
	55 - 64 years		4,98	<b>2,14</b>
	over 65 years		1,88	<b>0,81</b>

Although the values for QALYs with intervention are reduced from one stage of the disease to another and different according to the medical condition studied they are significantly higher than those for QALY without intervention that we calculated in a previous research (see Pantea and Gligor, 2012b).

Thus, the results validate our research hypothesis and allow us to substantiate that in terms of quality of life, healthcare investments have an important social and health impact.

## **5. Conclusions and discussions**

The reference point of our research is the study of optimal resources' allocation (especially the case of structural funds) for the production of benefits to the society. Since by definition, resources are limited, the healthcare systems faces this condition every day, aspect that led to the development economic evaluations as key component of decision making. In this sense, the need for a common measurement unit that allows comparisons between different sectors of healthcare and even beyond has conditioned new instruments for benefits appraisal including quality adjusted life year, indicator that serves as a tool in channeling public resources to health interventions imperative for the population.

As we previously underlined, our research and results are issues currently addressed only from a theoretical point of view. As demonstrated for two major medical conditions that affect peoples' quality of life and average life expectancy, QALY captures health gains generated by treatments.

The usefulness of our results comes from allowing guidance for the public prioritization process in terms of resource allocation by substantiating the process on forecasts of patients' clinical outcomes. Also, the information provided enables comparisons regarding the effectiveness of different medical interventions for the same health problem by estimating the duration and quality of life gained through treatment.

The limitations of our research arise from the relatively modest sample investigated, which might generate a low capacity to generalize the results. In this sense, our study opened opportunities for further research, such as widening the population investigated, calculating QALYs for other medical conditions that affect human health and calculating QALYs gained for the medical conditions targeted.

## ROMANIA'S ECONOMY AFTER THE EUROPEAN UNION ACCESSION

**Părean Mihai Olimpiu, Vădăsan Ioana**

[mihai.parean@feaa.uvt.ro](mailto:mihai.parean@feaa.uvt.ro)

[ioana.vadasan@feaa.uvt.ro](mailto:ioana.vadasan@feaa.uvt.ro)

**Abstract:** *If, during the communism, Romania had an unusual position at the European level, after 1989 it had a different path, in comparison with other former communist states: the country had the harshest difficulties finding its European path, then it had the most important economic growth rate; in the same time, it has been the candidate state facing many economic and social issues, which have worsened during the crisis. In this paper, the authors present the evolution of the Romanian economy, by analyzing representative economic indicators, the dynamics of the national economy, after its accession to the European Union (EU). It is obvious that the country's evolution has been influenced by the decisions taken and implemented during the pre-accession period. At first sight, it is very difficult to economically separate the two periods of time. However, one can notice that, after the beginning of negotiations (February 2000), Romania's economic policies have been implemented in a more sustained rhythm, due to the surveillance coming from the European authorities. After seven years of economic growth, which contributed to a partial catching-up with the European average, Romania became member of the EU, having a precarious economic and social situation. Under those circumstances, it would have been normal to continue to implement economic reform policies. Unfortunately, the determination of national authorities has sharply diminished after 2007. The first years of Romania's membership have been characterized by important rates of economic growth, due, among other factors, to favourable international circumstances. This contributed to an increased trust on the part of Romania's population and government in the national economy (even too optimistic). This, together with the fact that Romania had an unhealthy economic growth, contributed, after the outbreak of the crisis, to some powerful shocks for the population and for the economy as a whole (a sudden and rapid economic fall, wage cuts unwitnessed in other European economies, increase of expenditures taxes). The Romanian authorities had to make external loans (from the International Monetary Fund, the EU and the World Bank). In spite of those measures, the Romanian economy did not straighten out. Due to reasons less linked to the economy, those funds did not reach the intended purpose. On the contrary, the Romanian economic and social environment had severely worsened. In the meanwhile, as the EU was facing its own issues, it had adopted firm measures to deal with it. Romania had to accept those measures (for instance, the Fiscal Treaty).*

**Key words:** Romania's economy, European Union, economic growth, economic crisis.

**JEL classification:** F43, N14, O11, O52

## 1. Introduction

The 1989 Revolution brought for Romania, as well as for the other Central and Eastern European countries, an important change in conceiving and acting in the economy, and in the society, generally. One can say that this has been a *changing process without solid theoretical bases, except for some inspirational ideas in different government programs* (Marin, Socol, Niculescu 2005: 4). One can appreciate this has been a *revolution without an ideological program*.

After Romania had been invited to start the accession negotiations (during the European Council hold in December 1999, in Helsinki), the European Union has urged the national authorities to accelerate the social and economic reform measures.

The relations between Romania and the EU have been quite difficult during the pre-accession period. The European officials knew that, where the Romanian strictness was well beyond the European strictness, there was a very large possibility for compromises. One can say that, at first sight, the EU has been very vigilant regarding our country's transformation during the pre-accession period (and even before, starting with the year 1997). Our accession date has been delayed, in comparison with other states, because the developing gaps were too large; in 1999, a medium term strategy has been adopted, allowing the EU and the international financial organization to guide the Romanian economy, still under the state control, and to build a free market (Părean 2013: 539). For the national economy, this period of time can be characterized by a sustained economic growth, allowing the catching-up in comparison with the EU average (a complex analysis has been done by Virginia Câmpeanu and it is presented in Mureșan 2008: 419-448). This catching-up process continued in the years 2007 and 2008, and it has been the best reflected in the evolution of the Gross Domestic Product/inhabitant (Murgescu 2010: 476).

## 2. Economic Growth after EU Accession

The catching-up process is, indeed, obvious, but, in spite of that, in the moment of our accession to the EU, Romania had an economic development level slightly superior to a third of the European average, and approximately 30% of its population lives in a subsistence agriculture (Cerna 2011: 2).

After a period of sustained economic growth, one can identify the following economic risks. In 2007, the accession moment, among the 15 EU poorest economic regions, six were in Romania. The poorest EU region is the North-Est Region, in Romania; in fact, the only Romania region not included in the category "very poor" is București-Ifov, having a GDP/capita of 74% in comparison with the EU average (Rădulescu 2008).

The reform programs implemented after 1989 cannot be characterized by consistency, the adopted measures produced just partially the anticipated effect, which entailed negative effects on the social level, deteriorating the population's living standard. The Romania's difficult situation is reflected by the existence of some major economic and social risks (Părean 2009: 200), like: the part of the external debt in the GDP – medium risk; the excessive growth of loans granted by the banking system – medium risk; the low level of GDP/capita – major risk; the labour productivity – major risk; the increase of the deficit of the current account, especially due to the trade deficit – major risk; other social risks: demographic decrease – major risk; resources allocated for the health insurance programs – major risk; pensions of

retired people, in the state system – major risk; governmental resources allocated for education, health, infrastructure and research and development – major risk.

After its accession, Romania has been a drab member, having neither personality nor initiatives (Boia 2012: 104).

Another important aspect for the Romanian economy, before and after the accession, is related to the relaunching of the internal production, based on the foreign direct investments. Thus, the labour productivity increased significantly, the gap in comparison with the EU average being partially caught-up. If in the year 2000, Romania's average labour productivity represented 28.8% in comparison with EU 25 labour productivity, by 2006 this indicator has reached 38.8%, and by 2008 it has reached 46.6% (\*\*\*- *România în cifre* 2009: 79).

EU has brought Romania important benefits: it has forced the institutions' modernization, it has brought foreign direct investments and economic prosperity. But the local capital is still fragile, the resources' allocation is not compatible with the strategy of sustainable development (Romania exported highly qualified labour force), and the market dominant positions have multiplied. Economic disequilibria have increased, in 2008 the deficit of the current account exceeded 12% of the GDP. Even worse, the savings did not sustained high productivity investments. In 2008, the gross investment exceeded 30% of the GDP (Dăianu 2012: 222), but their structure raises important issues (for instance, there aren't important infrastructure projects – highways, railways, harbors, or important land projects).

The first two years after the accession, the macroeconomic indicators showed a good situation, which contributed to the catching-up process towards Western Europe (table 1). In 2008, although GDP increase was significant, one can notice that the economic crisis started to hit the national economy: unemployment, budgetary deficit and external debt have increased, while the labour productivity has decreased.

**Table 1.** The Dynamics of main macroeconomic indicators, for 2007 - 2008

	GDP (%) yearly variation)	Annual average inflation rate (%)	Unemployment (%)	Budgetary deficit (%) of GDP)	Deficit of payment balance (% of GDP)	External debt (%) of GDP)	Labour productivity (2000 = 100)
2007	6,0	4,8	4,1	-2,6	-13,5	47,5	181,4
2008	7,3	7,8	4,4	-4,8	-12,3	49,1	170,5

Source: \*\*\* - *Anuarul Statistic al României*, 2011

The post-accession strategy, adopted by the government at the beginning of 2007, had, as objectives, to create a framework, favorable for infrastructure development (transports, IT, energy, environment), to develop the human capital, to promote the research and development, to consolidate the market economy mechanisms, etc. (Murgescu 2010: 480); unfortunately, all these objectives were not achieved.

After a sustained economic growth, due to procyclical economic policies, the economic recession could not be avoided. However, one must take into consideration that the catching-up process is a slow one and that a total caught-up rarely takes place. The management of the economic policy doesn't need to be extraordinary, but determined, with serious and capable people, doing their job, taking on obligations and following them through, discretely and responsively

(Părean 2013: 549). The measures they adopt have to avoid social polarization (Derek Aldcroft was severely criticizing the situations where fiscal and redistributive state policies “tend to favor a small minority, to the disadvantage of the big majority of the population [...], while distributing unequally the revenues and the wealth”, and thus the “governance is through and for elitist groups”) (Aldcroft, Sutcliffe 1999: 19). As a matter of fact, since 2007, the International Monetary Fund and the Governor of Romanian National Bank were warning against the risk of the over-heating of the economy (Alonso 2010). The danger was the increased inflation rate and the increased current account deficit (Escritt, Wagstyl 2007). In November 2007, *Standard & Poor* has reduced our country’s perspectives from *stable* to *negative* (Gallagher 2010: 271), and in March 2008 *Economist Intelligence Unit* (EIU) has warned that Romania is among Eastern Europe’s most vulnerable countries. The privatization process was largely concluded, and the foreign investors were no longer very interested in the Romanian economy; consequently, without foreign investments, it was almost impossible to take under control the current account deficit. The foreign investments did not contribute significantly to the increase of the labour market. In 2007, 49 private companies, with a turnover superior to 1 billion euros, were employing only 3.8% of the labour force (Șerbănescu 2008).

### **3. The Beginning of the Crisis and its Manifestations**

There is an intense debate regarding the causes of the crisis in Romania, after 2008. Some authors consider that, partially, the crisis has been imported, especially through the reduction of the external demand, and because of the reticent attitude of foreign investors while others consider as main cause the unsuitable governmental policies in 2007 and 2008. Other authors (Fota, Băcescu 2009:49-54; Voinea 2009: 63) have shown that, in fact, the causes of the crisis in Romania must be looked for exclusively inside the country, the international events having just contributed to the unleashing of the crisis.

The world economic crisis hit Romania in the second half of 2008 (officially, the crisis started on October the 1<sup>st</sup>, 2008). From that moment, the combination between the external deficit, the budgetary deficit and the reduction of financial flows led to important economic disequilibria, at the national level. Partially, the crisis had been imported (the reduction of external demand, the reticent attitude of foreign investors), but a big contribution can be given to internal side-slips.

Unfortunately, in Romania, in the last decade, the government has implemented mainly procyclical policies. During periods of economic growth (in 2005), one has adopted the flat rate tax, encouraging the business sector, while in 2009, during economic recession, the government introduced the minimum tax for the business sector. This led to the closure or suspension of an important number of small and medium sized enterprises (table 2).

**Table 2.** The dynamics of the business sector after the crisis beginning, in Romania

Indicator \ Years	2009	2010	2011
Number of closed enterprises	57041	49092	13290 (sem I)
Number of suspended enterprises	127129	139139	22062 (sem I)

Source: [www.onrc.ro](http://www.onrc.ro), accessed on December the 15<sup>th</sup>, 2012

Certainly, those measures are justified, but we can say that in Romania, only short-term objectives have been followed, while medium- and long-term objectives have been neglected, although these objectives should have been decisive for the economic policy. In 2005, Romania had the historic chance to partially catch-up the gap in relation to the EU average, and the perspective of EU accession has encouraged stimulation actions for the business sector. After the crisis, through the economic measures taken, the government wanted to equilibrate the national budget, and the minimum tax system was intended to clean the Romanian business environment. But this measure reduced even more the economic recovery potential, having negative impact upon the Romanian economy and society.

The difficult economic and social situation in Romania, after 2009, is presented in table 3. The first two years reflect the massive effect of the crisis. We can see that after years of strong economic growth, a strong recession followed. The value of loans has constantly increased, but in the same time, the arrears in repayment have increased as well. As for the public debt, Romania still has one of the most reduced public debts in Europe. However, we can notice that the tendency indicates an increase of the public debt.

The decrease of the unemployment is, on the one hand, encouraging. But, on the other hand, this reduction was possible because many people have left the labour market (through retirement, for instance). And this led to another difficult issue: the considerable increased numbers of pensioners, deterioration of the ratio between active persons and dependent persons, generating a structural deficit of social insurances budget.

**Table 3.** The evolution of some indicators for the economic situation of Romania during the crisis (2008 - 2012)

Indicator \ Years	2009	2010	2011	2012
Economic growth rate – real GDP(%)	-7,1	1,3	2,2	0,3
Inflation rate (%)	5,6	6,1	5,79	4,9
Public debt	147,3	194,5	223,3	241
Governmental public debt (billion RON)	136,5	182,5	210,4	227,2
Public debt as percentage of GDP (%)	29,4	37,2	38,6	40,2%*
Value of loans (billion RON)	198,9	207,9	225,16	?
Value of arrears in repayment (billion RON)	5,9	13,9	21,32	24, 72 (1 <sup>st</sup> semester)
Unemployed people (thousands of persons)	731	714	460	493,8
Unemployment rate (%)	7,8	6,97	5,12	5,59

\* estimated

The inflation rate has increased in the first two years (2009 and 2010), but then a disinflationary trend has followed. However, the target, in terms of inflation rate, has not been reached: until the end of 2012, the annual inflation rate had been of 4.95%, higher with 0.95% than the target for 2012 (Raport asupra inflației 2013:8).

After having officially acknowledged the crisis, the national authorities adopted a program to fight against its undesirable effects. *Action Plan for Economic Growth and Jobs* has been adopted by the end of 2008 (November) and had many stipulations. Three measures referred to a fiscal relaxation, one measure to job creation, seven measures were aimed to stimulate the aggregate demand (by increasing the government expenditures with goods and services) and the aggregate supply (by stimulating the private investments), others were administrative measures, for a better coordination of activities within the economy, regarding a better absorption rate of structural funds, or regarding the insurance in the economy of necessary capital flows by the private banks.

On March the 29th 2009, Romania signed a borrowing and assistance agreement with international financial organizations. The borrowed amount of money was of 19.5 billion Euros, following the agreement with IMF, European Commission, European Bank for Reconstruction and Development, and World Bank. Romania used 11.8 billion euros in 2009, 7.1 billion euros in 2010 and 1.05 billion euros in 2011.

The conditions imposed to Romania referred to deficit control actions. The restrictive financial policy led to a spectacular cut of current account deficit (from 16157 million Euros in 2008 to 5054 million euros in 2009, especially due to a reduction of imports, by more than 12.3 billion euros) (Murgescu 2010: 478).

In 2009, the most important relaunch measure was the Program “The First House”, having a very important budget for the first stage (approximately 1 billion euros for 2009). Although this program had several stages, it did not stimulate the construction sectors, people preferring to buy apartments already built, instead of new apartments.

In 2009, the difficulties of the Romanian authorities were obvious. During the last two months of the year, the employees in the budgetary system had an unpaid vacation of 5 days, or had to work without being paid (a form of partial unemployment). But the toughest measures had been taken in 2010, when the wages of the employees in the budgetary system had been cut by 25%, and the value-added tax increased by 5% (from 19% to 24%)

At the beginning of 2012, Romania signed the Fiscal Discipline Treaty, taking on the obligation of increasing the budgetary discipline. This Treaty aims to solve the issues of the Euro zone. In the same time, we must take into consideration the fact that our country’s situation depends on a positive solution for the Euro zone. This is not a fiscal integration, so we can say that the monetary union is not a complete one without a common treasury. According to the Fiscal Treaty, the structural deficit must be of maximum 0.5% of GDP. In Romania, this deficit was superior to 3% of GDP, and in 2008 it has been of 8%. In order to reach the target, a fiscal and structural correction of 3% of GDP is needed, which is considerable, especially taking into consideration that our fiscal revenues represent 28-29% of GDP (Dăianu 2012: 211). Of course, the immediate effects are negative, but positive effects are expected on medium- and long-term. One can also consider that implementing such an agreement represents a high limitation of the capacity of the fiscal policy to stimulate the activity of economic agents. A structural deficit of 0.5% of GDP means that the actual deficit should be close to zero, on the long-run. Given the fact that, in Romania, the interest rates of the public debt represent 1.7%-1.8% of the GDP, this means that the budget, before the payment of the interest rates for the public debt, must register a surplus.

#### **4. Conclusion**

After 1989, Romania has been long looking for its own path, more than other former communist countries. After the accession negotiations began, Romania had many benefits. Between 2000 and 2008, it had the biggest economic growth rate in Europe: this period of time has been the only one, in over 200 years, when Romania partially caught-up its development gaps, in comparison with the European average. This is an important thing to be mentioned, given the major differences between our national economy and the economies of other West European countries. Even more, the West European structures had a major and positive impact upon the Romanian economy and society.

In Romania, the way of thinking and acting has been seriously influenced by the communist inheritance. Unfortunately, Romania had a certain reserve in immediately and accordingly implementing the necessary economic measures, which would have contributed to a healthy and performing economy. This seems to be a paradox, especially taking into consideration the optimism and confidence of the population in the Western structures. It is obvious that there is a huge difference between people’s desires and politicians’ desires. As a matter of fact, just as Lucian Boia notices, the Romanian politician is also a business person. Thus, in implementing the economic measures and European directives there was not much of an enthusiasm, and in the

moment of EU accession, Romania seemed to be a country with a less successful economic reform, partially due to the fact that the European authorities did not pay too much attention to the way of implementing the reforms (in that sense, Tom Gallagher noticed that the Romanian authorities managed to “balkanize” the Westerns).

If, during the accession negotiations, there was a sustained rhythm of implementing the economic reforms, after the accession this rhythm became much more relaxed. After 2007, our country’s economy continued to have high economic growth rates, but mainly due to the fact that Romania was now part of a select economic group, allowing us to have a low country risk and to attract foreign investors. Also, the lack of authentic reforms lowered the price of certain economic resources, thus keeping the country attractive. After accession, the economic reforms have almost stopped. Consequently, after 2008, in a crisis context, most economic indicators for Romania have worsened, and the financial situation has considerably deteriorated. The increase of budgetary deficit was the expression of a reduced economic activity, but also of unwise economic policies from previous period of time. The result was the unpopular measures taken in 2010, in order to rebalance the national budget. Unfortunately, those decisions had an adverse effect, by strongly disequilibrating the households’ budgets. Those measures were intended for a short period of time (6 months), in order to take the necessary measures to stimulate the economic activities. But the measures failed. And the evolution of the external environment did not help Romania.

The social negative evolution is the direct effect of a reduced GDP, of a reduced power purchase of households, and an indirect effect of revenues redistribution methods aimed to favor limited interest groups, to the disadvantage of a vast majority of the population.

## IS THERE ANY RELIABLE COMPASS FOR TRACKING EU MEMBER STATES COMPETITIVENESS?

**Popa Angela Cristina**

Academy of Economic Studies, Bucharest, Romania

[popacristina85@yahoo.com](mailto:popacristina85@yahoo.com)

**Abstract:** *Competitiveness has a variety of definitions that lead to different indicators, each with its own particular application. Moreover, for any single concept of competitiveness, several measures may be constructed, depending on further specific assumptions. No single measure, or limited set of measures can provide all the information required to assess and manage an economy. In this paper we decided to construct two composite indices to assess two dimensions of competitiveness: one called simply economic robustness and the second one called price competitiveness. Almost all the time the decisions we make depend on what we measure, how we do our measurements and how we interpret them. To construct the composite indices we applied an exploratory factor analysis which is based on the idea that strongly correlated indicators refer to the same underlying (latent) dimension. Thus, a data set consisting of many indicators can be reduced into a single or a small number of composite variables (the so-called factor scores), each reflecting a significant part of the total variance. The indicators included in our analysis are: GDP per capita, domestic demand, private consumption, governmental consumption, gross fixed capital formation, harmonized index of consumer prices (HICP), Labor Cost Index (LCI), Industrial Production Index (IPI), export of goods and services, import of goods and services, real effective exchange rate (UCL based) and population and the data were collected for all EU Member States in the year 2010, as they are considered to track wealth and economic growth, indicate economic robustness and correlate with countries competitiveness. After constructing the composite indices, we tested their robustness throughout a pooled OLS (Ordinary Least Squares) regression on the GDP per capita, as the dependent variable. The outcomes proved to be significant and having the expected signs. The conclusions highlight that among countries that were characterized by high economic robustness in 2010 are Germany, Spain, France, Italy, Netherlands and United Kingdom, while among the countries that performed poorly we can mention Malta, Estonia, Bulgaria and Romania.*

### 1. Introduction

The term “international competitiveness” has been associated over time with different definitions and senses, being at the moment one of the most controversial topics. Although some economists argue that competitiveness is generated at the microeconomic level, the level at which it is sustained and reinforced is the macroeconomic level, although, at the macro-economic level, the concept of competitiveness is much more poorly defined and more strongly contested. The lack of a commonly accepted definition is by far one of the most important source of opposition to the concept of macro-economic competitiveness or international competitiveness.

In an increasingly globalizing world, most countries are integrated into the world economy, voluntarily or by force. International competitiveness has to be in this context both reflected by internal and external performances. We cannot say that a country is competitive if its living standards are low although its cheap products are sold worldwide; and also it is not common for a country to enjoy a high living standard if it doesn't have any internationally competitive products, firms or industries. There are a variety of definitions of competitiveness that lead to different indicators, each with its own particular application. Moreover, for any single concept of competitiveness, several measures may be constructed, depending on further specific assumptions. No single measure, or limited set of measures, can provide all the information required to assess and manage an economy. These measures range from indicators of economic performance, single-factor indicators based on price or cost development, to composite indices reflecting economic, structural and institutional factors.

The problem of national competitiveness is extremely important in the context of countries accession to the Economic and Monetary Union, as future member states must integrate into a competitive economic area. Thus, in this paper we decided to construct two composite indices to assess two dimensions of competitiveness: one called simply economic robustness and the second one called price competitiveness. To construct these indices we applied an exploratory factor analysis which is based on the idea that strongly correlated indicators refer to the same underlying (latent) dimension, so that a data set consisting of many indicators can be reduced into a single or a small number of composite variables (the so-called factor scores), each reflecting a significant part of the total variance. We considered 12 significant variables: GDP *per capita*, domestic demand, private consumption, governmental consumption, gross fixed capital formation, harmonized index of consumer prices (HICP), Labor Cost Index (LCI), Industrial Production Index (IPI), export of goods and services, import of goods and services, real effective exchange rate (UCL based) and population and we collected our data for all EU Member States in the year 2010. After constructing the composites, we tested their robustness by regressing them on the GDP *per capita*, as the dependent variable. The outcomes proved to be significant with the expected signs.

The plan of the paper is as follows: the following section reviews the empirical literature in the field of international competitiveness; section 3 presents the construction of the two composite indicators developed in this study based on the considered variables; section 4 presents the methodology chosen for our data and section 5 reports the data and main findings. The outcomes are highlighted in the last section of the paper.

## **2. Related literature**

Many economists seem to think that like trade performance, living standard alone does not give a complete answer to the competitiveness question hence they combine issues of external balance and domestic performance (Aiginger, 1998), which Fagerberg *et al.* (2007) calls the "double meaning" of national competitiveness, i.e. trade performance and economic well-being of citizens. In this sense, many studies developed different methodologies in order to measure the many dimensions of competitiveness or to capture the overall effect of the international competitiveness. Even though some institutions have taken a broad view with an emphasis on the overall competitiveness and others have focused on

the competitiveness of the external sector, the most commonly used research methods in this field are still quantitative, many researchers choosing the indexing and classification method. The same methodology is applied by the two well-known institutions *WEF (World Economic Forum)* and *IMD (International Institute for Management Development)* which are first building an index of national competitiveness (by compiling individual sub-indicators into a single composite indicator), then calculate each country's score based on the indicator and classify the countries based on the scores obtained. There are also several institutions that monitor countries competitiveness using both macro and micro-based competitiveness indicators. The EC publishes annually the "*European Competitiveness Report*" (2012) which analyzes recent developments of overall competitiveness performance of the European Union (EU) and the impact of economic reforms on productivity. The Organization for Economic Cooperation and Development (OECD) also studies the impact of policies on labor productivity in member countries in its annual publication entitled "*Going for Growth*" (2011). The IMF regularly reviews competitiveness developments as part of its Article IV surveillance exercise of member countries, while the World Bank has developed also international rankings of countries using competitiveness indicators which have a microeconomic focus.

In the paper called "*How much did competitiveness of the Greek economy decline since EMU entry?*" (Malliaropulos, 2010) the author construct sectorial indices of price and wage competitiveness and combine them into two aggregate indices of Real Effective Exchange Rates (REERs) in order to assess Greek's competitiveness in terms of relative prices and unit labor costs. Although manufacturing and international trade in goods have traditionally represented a basis for the calculation of exchange rate indices or national price competitiveness indicators, this approach is however too narrow to measure macroeconomic competitiveness of a country – especially in developed economies where the service sector has a growing trend (Magerl and Mooslechner, 2006). Until recently, there was a lack of reliable indicators that could be used to put numbers on the so-called many dimensions of competitiveness, emphasized by the theoretical literature. But in recent years, the availability and quality of different aspects of development improved significantly, giving researchers new opportunities to investigate the differences in economic performance among countries, by integrating large amounts of information into easily understandable formats, like for example, composite indicators (Freudenberg, 2003). As Joseph Schumpeter (Schumpeter, 1943) already stated, price or cost competitiveness are left behind by other measures of competitiveness, like new commodity, new technology, new sources of supply and new type of organization. Fagerberg (2007) also constructed two composite indices to assess technological competitiveness and the capacity of countries to exploit such competitiveness. He based his composites on several reliable indicators and applied a confirmatory factor analysis in order to give weights to the variables in the composite. Further, he tested their robustness using cross-sectional data for a large number of countries, and the reported results were arguably consistent with other lessons from the literature. In the paper "*Measuring External Competitiveness: An Overview*" (Leichter et al., 2010) the authors are assessing Italy's external competitiveness, using a large number of indicators and comparing Italy's competitive position among the major OECD countries in 2006 (pre-crisis) and 2008 throughout a Principal Components Analysis (PCA), a methodology to synthesize much of the information contained in a number

of observed variables in terms of a smaller number of unobserved variables. Although preliminary, their results showed that the variation in Italy's competitiveness was left relatively unchanged by the crisis.

### **3. Methodology**

Almost all the time the decisions we make depend on what we measure, how we do our measurements and how we interpret them. The indicators considered in this section are: GDP *per capita*, domestic demand, private consumption, governmental consumption, gross fixed capital formation, harmonized index of consumer prices (HICP), Labor Cost Index (LCI), Industrial Production Index (IPI), export of goods and services, import of goods and services, real effective exchange rate (UCL based) and population and were collected for all EU Member States in the year 2010. These indicators serve several purposes but first of all they are considered to track wealth and economic growth, indicate economic robustness and correlate with countries competitiveness.

GDP, as a key concept of macroeconomics, reflects the market value of all goods and services intended for final consumption, produced in all branches of the economy in a country in one year. It can serve as a measure of well-being of a country and also provide a good first approximation for international and temporal comparisons. It is well known the fact that, domestic demand, as a component of GDP can influence economic growth by stimulating economic activities and can generate jobs and increase production capacity. Because GDP combines the sum of all activities that can be assessed in money and not their usefulness (or even their destruction) means that GDP is not a complex tool for measuring well-being and quality of life, which is why we have introduced in the analysis the two components of consumption. Another adequate indicator used in the present analysis is gross fixed capital formation, giving a measure on the expenditure on capital goods (durable goods) purchased by the productive units to be used for at least one year in the production process, as well as the value of homes purchased (or built) by population. Harmonized Index of Consumer Prices (HICP), as a weighted average of price indices of member states who have adopted the euro serves at maintaining price stability in the Euro Area and is also used to assess the convergence criteria on inflation that countries must fulfill in order to adopt the Euro. The Labor Cost Index (LCI) measures the cost pressure arising from the production factor "labor", while the Producer Price Index (PPI) measures the average change over time in the selling prices received by domestic producers for their output. Total exports gives information about the foreign demand for goods/services produced by the country in question, while total imports reflect how strong the domestic demand is. Increase or decrease of a currency in relation to another currency reflects the confidence of international economic entities in that country's economy (among other factors) as well as the degree of competitiveness of its exported products (a low exchange rate indicates a low price of the products and thus a competitive advantage). Real Effective Exchange Rate (REER) aims to assess a country's price or cost competitiveness relative to its principal competitors in international markets. Its importance stems from the fact that it can be used as an indicator for international trade competitiveness of countries. Because of its important role played in an economy, the real exchange rate has been one of the most controversial issues both in theory and practice.

The model developed in this paper takes into consideration the EU-27 countries in different stages of development, from highly developed countries (Germany, United Kingdom, Denmark, and Luxembourg), developed countries (Belgium, Czech Republic, Austria) and developing countries (Bulgaria, Romania, Poland). Not having a pre-defined idea about the structure or exact dimensions that are in our set of variables, we first employ an Exploratory Factor Analysis in order to get a small set of correlated variables. Based on the Exploratory Factor Analysis outcomes, we constructed two composite indices which we called “economic robustness” and “price competitiveness”, giving each variable an equal weight. To weight together a large number of individual variables into one composite indicator, we had to standardize the variables on a common scale. We did this by deducting the mean of the indicator and dividing it by its standard deviation. The “economic robustness” and “price competitiveness” equations based on the factor analysis are the following:

$$I_{ER} = (14,28 * EC_1 + 14,28 * DD + 14,28 * GC + 14,28 * PC + 14,28 * GFCF + 14,28 * EXP + 14,28 * IMP + 14,8 * POP)/100$$

$$I_{PC} = (50 * REUCL + 50 * HICP)/100$$

In order to test the robustness of the two composite indices, we estimated our model using a cross-sectional panel data regression with GDP *per capita* as the dependent variable.

The general form of the model is:

**The general form the Model:**

$$y_{i2010} = c + x_{i2010}\alpha + \varepsilon_{i2010}, \quad i = 1, \dots, N$$

$\varepsilon_{i2010}$  = residual disturbance term

**The model becomes:**

$$y_{i2010} = c + ec.rob_{i2010}\alpha + price_{i2010}\beta + \varepsilon_{i2010},$$

$i = 1, \dots, N; t = 2010$

$ec.rob_{i2010}$  = economic robustness of country  $i$

$price_{i2010}\beta$  = price competitiveness of country  $i$

$\alpha, \beta$  = parameters

$\varepsilon_{i2010}$  = residual disturbance term

#### 4. Empirical findings

It is obvious that the 11 variables are redundant and they cannot measure in the same time as many aspects of the economy. This is why we applied an exploratory factor analysis, to group the variables on a smaller number of dimensions. One of the most commonly used criteria for solving the number-of-factors problem is the eigenvalue-one criterion, also known as the Kaiser criterion (*Kaiser, 1960*). With this approach, you retain and interpret any factor with an eigenvalue greater than 1.00. Each observed variable contributes one unit of variance to the total variance in the data set and therefore any factor that displays an eigenvalue greater than 1.00 is accounting for a greater amount of variance and worth being retained. The proportion indicates the relative weight of each factor in the total variance. We can clearly see from the table below (*Table 4.1.*) that factor1, with an eigenvalue of 7.04284 explains 0, 78% of the total variance, while factor2, with an eigenvalue of 1.10248 explains 0, 12% of the total variance.

**Table 4.1. Total variance explained**

Factor	Eigenvalue	Difference	Proportion	Cumulative
Factor1	7.04284	5.94037	0.7880	0.7880
Factor2	1.10248	0.55257	0.1233	0.9113
Factor3	0.54990	0.30480	0.0615	0.9728
Factor4	0.24511	0.10746	0.0274	1.0003
Factor5	0.13764	0.12315	0.0154	1.0157
Factor6	0.01450	0.00404	0.0016	1.0173
Factor7	0.01046	0.01051	0.0012	1.0185
Factor8	-0.00005	0.00076	-0.0000	1.0184
Factor9	-0.00081	0.01301	-0.0001	1.0184
Factor10	-0.01382	0.13643	-0.0015	1.0168
Factor11	-0.15025	.	-0.0168	1.0000

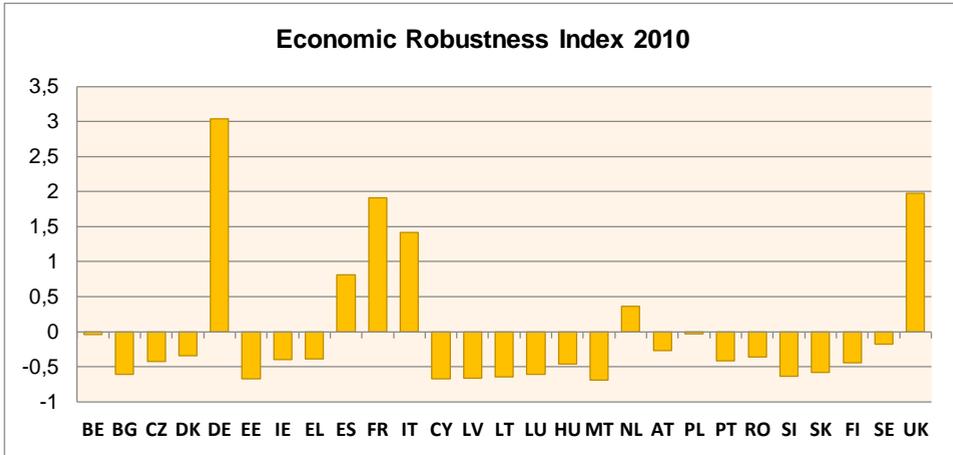

Having more than one variable loading on each factor, we grouped these variables according to the Rotated Component Matrix in *Table 4.2*. In the rotated component matrix, the variable's order is mixed, each of them explaining at least half of each original variable's variance. In this case, the communality value for each variable should be 0.50 or higher. Communalities represent the proportion of the variance in the original variables that is accounted for by the factor solution. A given variable will display a large communality if it loads heavily on at least one of the study's retained components. Thus, we have 7 variables loading on factor 1 and 4 variables loading on factor 2.

**Table 4.2. Rotated component matrix**

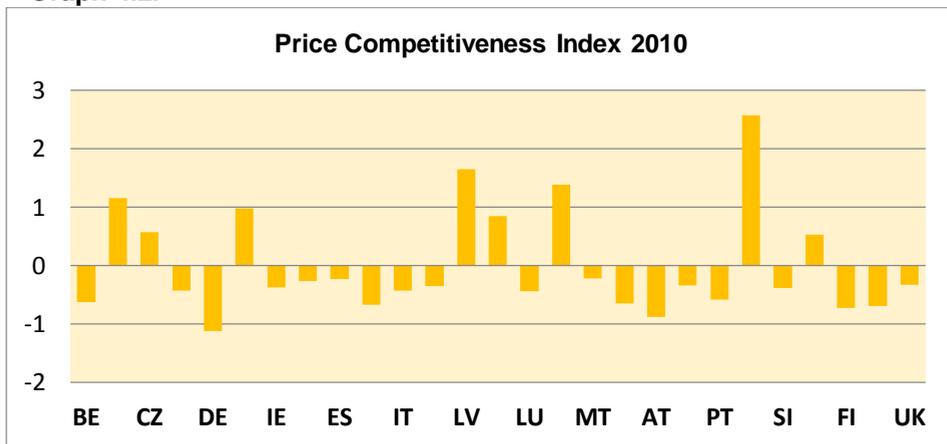

Variable	Factor1	Factor2
<i>DD</i>	0.9815	-0.1183
<i>REUCL</i>	-0.2598	0.6595
<i>GC</i>	0.9708	-0.1409
<i>PC</i>	0.9808	-0.1043
<i>GFCF</i>	0.9792	-0.1334
<i>HICP</i>	-0.2535	0.7201
<i>LCI</i>	-0.0128	0.1169
<i>IPI</i>	-0.1678	0.1471
<i>EXP</i>	0.9076	-0.2452
<i>IMP</i>	0.9440	-0.2198
<i>POP</i>	0.9698	0.0230

On first iteration, the communalities for the variables *LCI* and *IPI* for 2010 were less than 0.50, so we replicated the analysis removing the variables *LCI* and *IPI*. We decided to keep the *HICP* and *REUCL*, because in the Rotated Component Matrix table, their values increased substantially. Based on the two factors, we constructed two composite indices, the Economic Robustness Index and Price Competitiveness Index, giving each variable within the indicator an equal weight (*D. Archibugi & A. Coco, 2004*). The descriptive statistics based on the two indices are shown in Graph 4.2.

**Graph 4.1.**

**Graph 4.2.**

Although greater weights should be given to variables that are considered to have higher shares in the composite or that lower weights should be given to the highly correlated variables, our outcomes are still important for measuring the overall performance of countries. The robustness of the two indices will be tested throughout a pooled OLS (Ordinary Least Squares) regression on the GDP *per capita*, as the dependent variable. The outcomes of the estimated model are shown below:

**Table 4.3. Regression results**

<b>VARIABLES</b>	<b>OLS</b>
Economic Robustness	<b>1.008***</b> <b>(0.0261)</b>
Price Competitiveness	<b>-0.0530***</b> <b>(0.0148)</b>
Constant	<b>-0</b> <b>(0.0158)</b>
<b>Observations</b>	<b>27</b>
<b>R-squared</b>	<b>0.994</b>

Note: The dependent variable is GDP *per capita* (millions of euro, reference year 2005-at 2005 exchange rates)  $\beta$  values of the parameters are reported. \*, \*\*, and \*\*\* denote significance at the 10%, 5%, and 1% levels.

We controlled for heteroskedasticity using the Windmeijer corrected standard errors (option robust in Stata). The F test is significant at 10% level, meaning that our model is correctly specified and all the coefficients are different from 0. The coefficients of the two composite indices included in the model have the expected signs, significantly different from zero at 0,5% level of significance. With an  $R^2$  of 99,4% , the model explains 99,4% of the GDP variance. Although our model suffers from omitted variables, it does not invalidate our findings, the indicators in question being robust to this estimation. In our case, we can interpret the result as follows: when economic robustness changes by one unit, the GDP *per capita* will increase in average by 100% and when price competitiveness changes by one unit, then the GDP *per capita* will decrease by 5,3%.

## 5. Conclusions

The general issue of price competitiveness concerns the choice of price or cost measure used. Price and or/cost competitiveness reflects the traditional view on competitiveness, which emphasizes the potentially damaging effects of excessive price/cost growth on the economy. In our case the price competitiveness index includes two important components: the HICP which measures the price stability on one hand and REUCL based on unit labor costs which is commonly used for assessing countries' price competitiveness, mostly for industrial countries, on the other hand. In our study, economic robustness reflects the good or bad performance in terms of selected indicators and will vary in time and across countries and is likely to depend on the flexibility of factor markets and anti-crisis policy interventions. Although the outcomes of our analysis are still preliminary, they point out that among countries that were characterized by high economic robustness in 2010 are Germany, Spain, France, Italy, Netherlands and United Kingdom. Although the leader in assessing this dimension was Germany, with the highest value, United Kingdom, France and Italy were also amongst the countries with the best results. There are several countries that performed poorly and among them we mention Malta, Estonia, Bulgaria, Romania, although the lowest value of all countries belongs to Malta. In 2010, the overall trend among all countries in the sample was a low

economic robustness, and this might be explained in part by the sovereign debt crisis in Greece and other vulnerable countries. As for price competitiveness, the countries that performed well in terms of economic robustness are taking advantage of the price competitiveness as well. Although there are many countries with positive effects of the price competitiveness, their quantitative effects are rather low. There are also countries that lost their price competitiveness, lagging behind the countries in the sample and these are Romania, with the highest value, Bulgaria, Estonia, Latvia, Hungary, Poland, and Lithuania.

A basic conclusion underpinning these prescriptions is that exporters from Euro Area crisis countries underperformed. The strong deterioration in Germany can be explained by labor market policies intended to cushion the impact of the crisis on employment, while for France, Spain and Italy export growth were lagging behind, losing simultaneously market shares. The conclusions highlight that in 2010 most countries experienced either some deterioration in their position or remained relatively unaffected and the eight newest European Union members (Bulgaria, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, and Romania) already suffer from problems that dragged the GIIPS—Greece, Ireland, Italy, Portugal, and Spain—into crisis: loss of competitiveness, widening external deficits, and deteriorating public finances.

# A SNAPSHOT OF THE TECHNOLOGICAL COMPETITIVENESS OF COUNTRIES

**Popa Angela Cristina**

Academy of Economic Studies, Bucharest, Romania

[popacristina85@yahoo.com](mailto:popacristina85@yahoo.com)

**Abstract:** *It is well known that technology is a key factor for the economic progress and helps countries competing more successfully in markets for new goods and services. Technological competitiveness becomes this way closely related to the degree of innovativeness of a country. Although there are several indicators that measure directly the innovativeness of a country, there are still problems at the moment related to the availability of data. In this paper, we decided to assess the technological competitiveness of countries, based on a structural decomposition analysis of the patent shares on the world market. Unlike other authors who applied this methodology in their studies, we collected our data from the World Intellectual Property Organization (WIPO) Statistical Database, covering 12 years, from 2000 till 2011 and we took into consideration 35 technology subsectors in 33 countries (EU 27, China, Canada, Japan, US, Switzerland and Norway). This approach should highlight the countries' technological opportunities on the world level and measure their access towards sectors with high technological opportunities. Structural decomposition analysis points out the extent to which the shifts between technological sectors were induced by the changing technological environment on the world level. The analysis also shows the extent to which a country has an advantage/disadvantage from its past specialization pattern, having had a priori patenting activities in sectors that are now offering high opportunities and the extent to which the country deliberately moved into high opportunity technology sectors, or at least out of the industries with declining opportunities. The outcomes showed that technological development of countries on the world market played an important role for the patenting activity, being highly related to a well-developed infrastructure and pointed out that there are still a lot of European countries facing problems related to the technological infrastructure and technological capabilities. Countries that managed to keep their market shares high and also to increase their market shares over the years, while taking advantage of high opportunity sectors at the world level are the real leaders in terms of technological development. These countries are Japan, US, and China from the European states: Germany, France, Netherland, and Switzerland.*

**Keywords:** technological competitiveness; structural decomposition analysis; patent shares;

**JEL Classifications:** O31, O33

## 1. Introduction

It is well known that technology is a key factor for the economic progress. From new inventions like software, robotics and biotechnology, to improvements in manufacturing systems and processes, technology makes economies and societies more efficient and productive. Technology also helps countries compete more successfully in markets for new goods and services. Technological competitiveness becomes in this way closely related to the degree of innovativeness of a country. As

Michael Porter already stated, “companies can be highly productive in any industry- shoes, agriculture, or semiconductors- if they employ sophisticated methods, use advanced technology, and offer unique products and services” (Porter, 1998). Moreover, what he was trying to emphasize is that there is no low intensive industry or sector and that all sectors can be knowledge intensive and therefore can employ advanced technology. Although there are several indicators that measure directly the innovativeness of a country, there are still problems at the moment related to the availability of data. In this paper, we decided to assess the technological competitiveness of countries, based on a structural decomposition analysis of the patent shares on the world market. This analysis was first developed by Fagerberg and Solie and later improved by Laursen (1999). It has been also applied in some empirical studies in the literature assessing trade performance and structural competitiveness in different countries or within Euro Area (Ilzkovitz et. al., 2010). Unlike other authors who also applied this methodology in their studies, we collected our data from the World Intellectual Property Organization (WIPO) Statistical Database, covering the years 2000-2011 and we took into consideration 35 technology subsectors in 33 countries (EU 27, China, Canada, Japan, US, Switzerland and Norway).

We followed the assumption that the technological gap between the developed the countries and developing ones represent an important path of development for the latter and that technology can also reveal trade patterns. This might be explained by the fact that technology accumulation lead to the development of technological capabilities that often makes export structures difficult to handle. (Lall, 1992, 2000). The outcomes of the analysis proved to be significant, highlighting the fact that technological development of the world market has an important role for the patenting activity of countries and that are also a lot of countries facing problems related to the technological infrastructure and technological capabilities. These descriptive statistics can serve as guide lines and directives for governments in drawing their goals towards improving the technological capabilities.

The plan of the paper is as follows: the following section reviews the empirical literature in the field of technological competitiveness and patents as a proxy for technological development, paying particular attention to patent shares decomposition; section 3 presents the applied methodology and section 4 reports the data and main findings. The outcomes are highlighted in the least section of the paper.

## **2. Related literature**

Patents have been used as a proxy for technological development in many empirical studies in the literature. The number of patents was used by Furman et al. (2002) and Furman and Hayes (2004) as a measure of the “innovative capacity” of a country. Although patents refer more to inventions rather than to innovations, and although they are used much more intensively in some industries than others, we can still consider them as an important base for advanced technology and intensive knowledge. Fagerberg (1987) also considered the patent statistics in constructing an index for technological development, in order to test the basic hypothesis of the technology gap theory and to analyze the differing growth performances of some industrial countries. He emphasized a positive correlation between the level of economic development of a country, measured as GDP per capita and the level of its technological development measured as number of patents. Although this proxy

can serve as a useful tool in understanding innovation, it is an imperfect measure because the propensity to patent varies considerably across industries, with many innovations not patented (or even not patentable). So, basing the entire analysis of the technological capability exclusively on this source might lead to a biased representation of the evidence. Although the concept of technological capability covers different aspects like: production capability, investment capability and innovation capability (Dalhman et. al. 1987), we decided to base our research only on patent growth rates in main technological sectors using the structural decomposition analysis. This methodology is based on the constant market share analysis, often used in empirical studies of trade (Fagerberg *et al.*, 1987; Laursen, 1999), but Laursen (1999) has also adopted this methodology for the analysis of the structural decomposition of patent shares over time at national level. This approach should highlight the countries' technological opportunities and measure a country's access to sectors with high technological opportunities at the world level. Structural decomposition analysis points out the extent to which the shifts between technological sectors of countries were induced by the changing technological environment at the world level. The analysis also shows the extent to which the country has an advantage/disadvantage from its past specialization pattern, having had a priori patenting activities in the sectors that are now offering high opportunities and the extent to which the country deliberately moved into high opportunity sectors, or at least out of the areas with declining opportunities. Furthermore, the analysis enables us to consider as exogenous the technological environment effects in the technology share effects and structural technology effects and as endogenous the country-level effects in the growth adaptation and stagnation effects. In the article "*Trade Performance and Structural Competitiveness Developments in the Euro Area: are Member States Equipped to meet the Globalization Challenges of the 21st Century?*" (Ilzkovitz et. al., 2010). the authors apply the structural decomposition analysis to the share of patents of Euro Area Member States on the world market, paying particular attention to the Euro Area as a whole. They concluded that there is a positive relationship between technology and market opportunities and those countries that are concentrating their innovative capacities in high-tech sectors are also shifting their production structures towards the sectors that are benefiting from the strongest growth in world demand. Among the methods in the literature that explore technology diffusion, we can mention patent citations and also patent maps. While the first refers to the fact that the more a certain patent is cited by subsequent patents, the more technology is considered to be diffused, implying that technology is more widely applied and thus more valuable (S.B. Chang et. al., 2009), the second one is part of the visualization methods and is considered to be proper for representing patent information and its analysis results (Y. G. Kim et. al., 2008). Visualization methods for patent analysis are called broadly a patent map. A patent map is the visualized expression of total patent analysis results to understand complex patent information easily and effectively. This is produced by gathering related patent documents of a target technology field, processing, and analyzing them (WIPO, 2003). Patents are useful sources of knowledge about technological progress and innovative activity (Park et al., 2005) and up until recently, patents, as a means to protect inventions legally, were perceived to be only for technology intensive sectors (Bader, 2008), but as Michael Porter already emphasized, "all industries can employ advanced technology; all industries can be knowledge intensive" (Porter, 1998). A conclusion from this would be that the value of firms,

especially in the knowledge-intensive business service sector is determined by the value of their intellectual property that can be represented and protected by patents (Hanel, 2006) and therefore more firms are trying to protect their service innovations (Bader, 2008). Nowadays patenting business models and software solutions seems to be quite common, especially in the US and Japan, countries that are practicing this for quite a while.

### 3. Methodology

Having discussed the role played by technology for the technological development of a country, in this section we apply the structural decomposition analysis of patent shares for a number of 33 countries. We chose to consider the EU 27 and also other 6 major economic powers of the world. The data were collected from the World Intellectual Property Organization (WIPO) Statistical Database representing the number of patent grants of a country by technology. The data covers 35 technology subsectors and were collected for the years 2000-2011. Although by adjusting the number of patents by country size we would have obtained a more reliable indicator (large countries tend to patent more than small countries), we can still make a relevant interpretation of the analysis using as a proxy the total number of patent grants. In many empirical studies, the number of patents is considered a proxy for the degree of technological development of a country. Therefore, in this section we apply the decomposition analysis in order to assess the level of technology of a country. Even though nor a single measure, or a limited set of indicators can provide all the information we need to assess the technological performance of a country, there is still a need to see to what extent are the technology patents capable of stimulating technological development. The decomposition analysis is as follows: We define the share of patents of country  $j$  in total world patents as:

$$v_j = \frac{\sum_i P_{ij}}{\sum_i \sum_j P_{ij}}, \quad (1)$$

Where:  $\sum_i P_{ij}$  = total patents of country  $j$

$\sum_i \sum_j P_{ij}$  = total patents on the world market

Also, the share of world patents of a country depends on its share of patents  $y_{ij}$  in sector  $i$  as well on the relevance of sectors  $i$  in the world patenting activity  $w_i$ :

$$y_{ij} = \frac{P_{ij}}{\sum_j P_{ij}} \quad (2)$$

Where:  $P_{ij}$  = total patents of country  $j$  in sector  $i$

$\sum_j P_{ij}$  = total patents on the world market in sector  $i$

$$w_i = \frac{\sum_j P_{ij}}{\sum_i \sum_j P_{ij}} \quad (3)$$

Where:  $\sum_j P_{ij}$  = total patents on the world market in sector  $i$

$\sum_i \sum_j P_{ij}$  = total patents on the world market

The change in a country's share of world patents can be further decomposed in three main elements:

$\Delta v_j = v_j^t - v_j^{t-12} = STE_j + TEA_j + TSE_j$ , (4) where  $t$  is the final year (2011) and  $t-12$  is the base year (2000).

$STE_j = \sum_i y_{ij}^{t-12} * \Delta w_i$  (5) is called the structural technology effect and measures the change in country  $j$ 's share of world patents, when the shares of its individual sectors remain constant over time. This indicator points out the direction of change and shows weather the country is gaining or losing patent shares, as a consequence of

its initial specialization in sectors that have developed their own technology and therefore patent more at the world level. Thus, this effect will be driven by the change of technological opportunities at the world level and will reflect the advantage/disadvantage in terms of overall evolution of the world patent shares, as a consequence of countries historical specialization pattern.

$TAE_j = \sum_i \Delta y_{ij} * \Delta w_i$  (6) is called the technology adaptation effect and measures the variation of the technological activities of country  $j$  within a sector  $i$  according to the changes in global patterns of technological opportunities. A positive technology adaptation effect means that the share of country  $j$  patents increases in sectors with a growing share on world patent activity, while a negative one suggests that the share of country  $j$  patents decreases in sectors with a growing share on world patent activity, meaning that country  $j$  is moving out of the sectors with high technological opportunities.

To shed more light on the situation in which a country increases or decreases its shares in both high (expanding) and low (declining) technological opportunities we further decompose this term into two distinct indicators (Laursen, 1999).

$$TAE_j = TGAE_j + TSAE_j \quad (6),$$

Where:  $TGAE_j = \sum_i \Delta y_{ij} \frac{\Delta w_{ij} + |w_{ij}|}{2}$  (7) is called the technology growth effect and is different from 0 only if  $\Delta w_{ij} > 0$  (if sector  $i$  has high technological opportunities at world level). A positive value shows that country  $j$  is moving into the sectors with high technological opportunities while a negative value shows that country  $j$  is losing patent shares in the sectors with high technological opportunities at the world level.

And:  $TSAE_j = \sum_i \Delta y_{ij} \frac{\Delta w_{ij} - |w_{ij}|}{2}$  (8) is called the technology stagnation effect and is different from 0 only if  $\Delta w_{ij} < 0$  (if sector  $i$  has low technological opportunities at world level). A positive value shows that country  $j$  is moving out of the sectors with low or declining technological opportunities, while a negative value shows that country  $j$  is gaining patent shares in sectors with low technological opportunities.

And the last indicator,  $TSE_j = \sum_i \Delta y_{ij} * \Delta w_i^{t-12}$  (9) is called the technology share effect and measures the change in patent shares of country  $j$  on the world market when the world patent structure remains fixed over time. In our case we consider the year 2000 as a base year for the world patent activities. So, if the structures of world sector patenting activities remain the same over the years, this effect can be interpreted as the “technological competitiveness” of country  $j$ . There are a lot of factors related to the so-called technological competitiveness that might trigger down or stimulate the gains or losses of patent shares. As some authors already emphasized in the literature, competences and quality of the human resources, the specialization in the high-technology sectors together with the development of the financial system seems to be important structural factors which are able to stabilize technological development (D.Archibugi et. al., 2010). The institutional framework plays also an important role for technological development, as there are many conditions that might conduct to innovation (R&D expenditures, access to venture capital, knowledge investments, the degree of product and labor markets flexibility, etc).

#### 4. Empirical findings

Table 4.1. highlights the results of the structural decomposition analysis of patent shares on the world market, based on the previously described methodology.

Table 4.1.: Patent shares and the rate of change of EU 27 countries, Norway, Switzerland, Canada, China, Japan and US on the world market (2000-2011)

Country	World patent share 2000	World patent share 2011	Total rate of change (%)

Author's calculations based on WIPO Database

First table (*Table 4.1.*) offers an overview of the share of patents on the world market and the rate of change of patent shares of countries during 12 years, from 2000 till 2011. The best performing countries in our sample are by far Japan and USA, with the highest patent shares both in 2000 and 2011, followed by China, Germany and France. Although the US patent share on the world market might be partially explained by the home bias effect, Japan is still the leader, increasing its patent shares over the years and having a patent share of 0,1548 in 2011. We can clearly see that the country with the best performance regarding the rate of change of patent shares on the world market was China, which increased its patent shares over the

past 12 years with 691,26%. Other countries which increased substantially their patent shares are Greece, Malta and Cyprus, but the big distances among their rates of change make us conclude that China was the leader in gaining patent shares on the world market. A good explanation found in the literature for the technological development of China might be that China have gained momentum after 2000 (Di Mauro and Forster, 2008) and passed from the stage of original equipment manufacturing (OEM) to the stage of original brand manufacturing (OBM) due to international knowledge, spillovers from multinational corporations, access to foreign markets and improvements in manufacturing systems and processes. It seems China's rapid technological development is no longer due to the fact that is considered an attractive location for assembly production based on high-tech imports or because of its capacity to imitate foreign technologies, but because China is a fast catching-up country in terms of high-tech sectors. Although Greece, Cyprus and Malta made large gains in percentage terms, their share of world patents remained very low in 2011. The country that registered the lowest increase in the patent shares on the world market was Canada (1,39%) , followed at close distance by Norway with 1,55%. On the other hand, among the countries that have suffered a negative growth rate we mention Bulgaria, with a negative rate of change of -85,73%, followed at close distance by Romania with a rate of change of -63,35%. *Table 4.2.* shows the results of the decomposition analysis of patent shares and highlights various technology effects. Looking at STE column we can observe an overall trend among countries of having a negative structural technology effect, which means that they experienced problems in catching-up with the world's technological trend. Still, there are 10 countries (Canada, China, Estonia, Ireland, Japan, Lithuania, Romania, Sweden, Switzerland and US) whose initial specialization didn't influence their global change in patent shares.

Author's calculations based on WIPO Database

Technological competitiveness (Technology Share Effect) has a major role in determining whether a country is losing or gaining patent shares. We can observe from the table 4.2. a connection between the technology share effect on one hand and the technology growth and technology stagnation effects on the other hand. Thus, the countries with a positive TSE effect have in the same time a positive technology growth effect and a negative or close to 0 technology stagnation effect. On the contrary, the countries with a negative TSE effect have a negative technology growth effect and positive or close to 0 technology stagnation effect, although there are a group of countries that have both technology growth and technology stagnation effects negative. The fact that technology share effect is negative means that the countries are losing overall patent shares and they are not technological competitive

at the world level. This is part confirmed by the positive correlation between the TSE effect and the technology growth effect and by the negative correlation between TSE effect and technology stagnation effect. The table shows a heterogeneous picture of the countries in the sample and pictures an overall trend between the countries that increased their patent shares over the years and moved into high technology opportunity sectors while gaining patent shares in the sectors with low technology opportunities. There is still one country which makes an exception from this pattern, and that is Slovakia, which despite the fact that it behaved according to the pattern, suffered a decrease of its overall patent shares.

## **5. Conclusions**

These descriptive statistics helps us determine the overall degree of technological development of countries in our sample. The technological development of the world market has an important role for the patenting activity of countries, being highly related to a well-developed infrastructure. The analysis points out that there are still a lot of European countries facing problems related to the technological infrastructure and technological capabilities. Countries that managed to keep their market shares high and also to increase their market shares over the years, while taking advantage of high opportunity sectors at the world level are the real leaders in terms of technological development. Among these countries we mention China, Japan, US, and for the European states Germany, France, Netherland, and not least, Switzerland. In 2000, EU27 had a patent share of 9,92% on the world market, while in 2010 its patent share remained relatively constant, with a slight decrease of 0,10. Japan was by far the leader in patent shares, both in 2000 and 2011, with a share of patents on the world market of 13,27%, respectively 15,49%. Another economic and technological power, the US, registered a patent share of 11,29% on the world market in 2000 and 10,31% in 2011. Although the patent share of EU 27 registered a slight decrease, it's lagging behind Japan in terms of technological development, measured throughout patents. A good example of catching up is represented by China, which increased its patent share from 0,51% in 2000 to 4,03% in 2011. Other countries outside EU27, like Canada, Norway or Switzerland had also significant patent shares, increasing their patent shares during these 12 years and consolidating their position on the world market. Although the U.S. and Japan are clearly the most technologically advanced countries in the world, other countries are making advances that may allow them to catch up to the U.S. and Japan in the future. China, India, Brazil are all countries that are making impressive technological gains. Even though U.S. is the leader in many different fields when it comes to technology, is surpassed by Japan when it comes to computer technology. Japan currently has the most powerful supercomputer in the world; the country with the second most powerful supercomputer is China, and the U.S. has the third fastest supercomputer. Japan also leads the way when it comes to consumer electronic technology; however, Japan trails the U.S. in all other areas.

The decomposition analysis also raises attention on several states that are performing very poorly regarding the patenting activity. These countries should concentrate on their overall capacity to innovate, to increase the R&D expenditures, to improve their institutional framework and undergo profound structural reforms. Deteriorating the patent shares of countries on the world market might hamper them in exploiting the potential to catch-up with the developed ones. What were considered up to now to be the problems facing by peripheral countries when talking about overall competitiveness is no longer true, at least not entirely true: their lack of

competitiveness vis-à-vis the developed countries is no due to the fact that their wages are substantially lower or that labor productivity has not increased. The reality is that they are stuck at middle levels of technology and they are caught in a trap. The outcomes highlighted by our approach can serve as an important proof that countries that attained high levels of patent shares are among the most technological competitive countries at the moment. The patenting activity and patenting infrastructure should represent an important goal for the countries government's and for their policy-makers.

adriana.radan@rei.ase.ro*

**Abstract:** *The movements on the world market suffered by the traditional textile industry bring us nowadays to reconsider the rebirth of the textile industry on new coordinates by the concentration of the latest technologies in order to satisfy the more and more demanding requests of the consumer. This paper tries to emphasize the idea that revitalization on a territory where there had been a strong development of a traditional textile industry in the past is possible now by configuring a new industry by means of some leader companies in their field of activity which create and develop new value sources with the advantages of the variant which integrates the latest interdisciplinary technologies, the so-called “key enabling technologies” (KETs), such as the microsystems, the smart materials, nano- and bio-technologies, and photonics. The KETs have a key role in creating the so-called industry of smart fabrics as it is shown in this summary case study for this very new born industry. All these technologies enable the appearance of some products fundamentally new of high interest, which furnish substantial economic advantages and involve industries with which they had no connection in the past. The main vectors in this effort of industrial transformation are the companies which are the best placed on the market of new industrial technologies generally called KETs, which combines the new ideas of economical organization through an intensive use of capital with the sustained effort of research-development, the usage of highly qualified labour force, and their geographical positioning at the points which best respond to their operational requirements. The competitive disadvantages of some countries with respect to the cheap labour force and the supply of raw materials essential for textile industry can be compensated by the re-orientation to the configuration of a new model of smart textiles and finally will contribute to re-launch the economic activity passing through recession, particularly in the areas more prepared from the point of view of high qualification and technical specialization.*

**Keywords:** KET; smart textiles; reindustrialization; competitiveness.

**JEL classification:** L67; O33; M16.

## 1. Introduction

Traditionally, the textile industry was developed based on the raw materials furnished by the agriculture and it used a labour force with the lowest qualification. These input features of industry expanded its geographical area to the zones with cheap labour force, which also had the capacity of satisfying the increasing demand of textile products at the global level.

As European Competitiveness Report (2012) shows due to the globalization, to the improvement of transport conditions and of technology, the production based on outsourcing enabled the strong optimization of costs and the development of

production relations so that various stages of the technological process are deployed at the most efficient locations on the globe, which ensure the best possible industrial performance. This process also features another characteristic: the sophisticated products are the least likely to be included in the outsourcing phenomenon. In the presence of crisis phenomenon, the companies also tend to reduce the outsourcing and to keep their business on the national territory as assistance between the local companies inside the value chain.

The changes on the global market imply the adaptation of business to the best condition of price, quality, innovation, but they should also take into account at the same time the environmental restraints and create their own development opportunities. This painting of the movements on the world market suffered by the textile industry in particular, brings us in front of the question whether it is possible the revitalization of this industry on a territory where there had been a strong development in the past. Theoretically, the revitalization is possible in two variants: by upgrading the traditional industry by using the already accumulated expertise or by configuring a new industry by means of some leader companies in their field of activity which create and develop new value sources (Chiarvesio et al., 2010).

This paper intends to present a summary case study for a very new born industry as an alternative to the traditional one which integrates the latest interdisciplinary technologies, the so-called “key enabling technologies”, such as the microsystems, the smart materials, nano- and bio-technologies and photonics and creates the so-called “smart fabrics” industry. From the beginning a definition for this industry will be developed for a better understanding of its determinants regarding the competitive advantage in the new context. Due to the effort of research-development implied, the best approach starts from the involvement of strong companies which can reconfigure the industrial landscape because of their presence on the market at a significant level. They would seek for the best location both on the international arena, and at the national level, in so-called clusters. The way they approach the business is studied in the following sections.

## **2. Smart fabrics: industry boundaries and key competitive determinants**

### **2.1. The theoretical approach of a general concept of industry**

Some studies (Ghemawat, 2010) show that generally the industry structure defines the business landscape through the conduct of the buyers and sellers. Michael Porter presented the “five forces” framework for an industry analysis which is made by suppliers, new entrants, industry competitors, substitutes and buyers, but the main problem of the industry definition is to draw the boundaries of the business landscape. Sometimes the boundaries should be the segments that the business operates or the technology can be the delimiter. Regarding the things in their dynamic, each Porter’s force can modify the business landscape and redraw new boundaries of the industry. When an industry becomes poor or less attractive, new opportunities get born by migrating to more attractive settings. For a single company it’s difficult to change the entire structure of the industry, but its action can open a door to a more attractive direction and other players on the market can use this as a management tool. The success or the failure for the new business is in fact the result of interactions among firm’s choices as parts of its strategy. For getting a competitive advantage the business must be different from another one and offer a higher value which has to be unique. Theoretically a competitive advantage over the rivals

“depends on driving a wider wedge between costs and buyer’s willingness to pay than one’s competitors can” (Ghemawat, 2010:64) but nowadays as Ralph Emerson anticipated “it’s better to strive for an edge over the competition” (Ghemawat, 2010:44). In our industry case, the “edge” means technology.

## **2.2 “Key Enabling Technologies”**

The contribution of these technologies means more than the increase of certain parameters of competitiveness. It actually means the appearance of some products fundamentally new of high interest, which furnish substantial economic advantages, thus responding to some of the most various requirements and involve industries with which they had no connection in the past.

From the conceptual point of view, KETs are defined in the European Competitiveness Report (2010) as incorporating a high percentage of research and development (R&D), the intensive use of capital and of a highly qualified labour force within extremely fast innovative cycles. They refer to the microsystems, the smart materials, nano- and bio-technologies, as well as photonics. The small and medium enterprises, by their development dynamics, are the vehicle by means of which these technologies manifest multidisciplinary, thus imprinting within their industrial area a character of convergence and integration. Many times, these enterprises develop in a large number within the so-called clusters, where the technological and commercial development enables their affirmation as key factors for the national development and creation of jobs. The central point of interest of an innovation project is the determination of a fair relationship between the research expenses and the capability of covering them by the sale price, an activity in which there are involved the business partners, the suppliers, distributors and customers. At the national level, there is streamlined the increase of productivity and welfare by the efficient use of the production factors and of the changes of industrial structure.

The following KETs concepts and statistical data are taken from the European Competitiveness Report on 2010, which used the information gathered in the period 1991 - 2005.

### **2.2.1. Nano-technologies**

Historically, they appeared in the 60s and they refer to the design, manufacture and use of structures at the molecular level, with dimensions smaller than 100 nm. The structures built at this scale feature electrical, magnetic, mechanical, chemical, biological, and optical characteristics much different from those at the macro scale. These changes of properties and characteristics are the engine of innovative power of the nano-technologies and they enable applications in all the fields where the materials are used. The most active zones in the world in the patent applications are Northern America, Eastern Asia, and Europe. In the rest of the world, the applications are at a low level. In Europe, Germany has the biggest number of application patents of the nano-technologies (34%), followed by France (17%), Great Britain (14%) and The Netherlands (8%). Without exhausting their huge potential, most of the products trade so far are currently based on the creation of nanostructures of carbon, silver and gold and metal oxides which have applications in all the fields, including the textiles.

In 2010, the Nobel Prize for physics was awarded for the discovery of a bi-dimensional structure of carbon atoms, which was called graphene. The structure has special mechanical properties which enable the resistance to extreme efforts,

being at the same time a very good conductor of electricity and transparent. The applications are in all the fields implying the use of materials with high resistance and which use very small quantities of raw material as it is shown at:

[http://www.nobelprize.org/nobel\\_prizes/physics/laureates/2010/advanced-physicsprize2010.pdf](http://www.nobelprize.org/nobel_prizes/physics/laureates/2010/advanced-physicsprize2010.pdf)

By comparison with the traditional textile industry which implies very high consumptions of raw materials, the use of these technologies allows a very small consumption of raw material with mechanical and electric properties higher than the traditional technologies.

### **2.2.2 Electronic Microsystems**

They refer to the highly miniature semiconductor components integrated in products with large physical volume. The miniaturization is a factor which reduces the costs, helps in the fast long range transportation and enables the transformation of any product into a so-called “smart” one. The recent successes in miniaturization actually meant the combination of semiconductor technologies with the field of nano-technologies, as the silicon structures decreased to dimensions below 100 nm. Countries in Eastern Asia started to dominate the patent market in this field from 2001, followed by Northern America and then Europe; the rest of the countries have limited values for being recorded by the statistics. In Europe, Germany dominates by 41%, and then France 16%, The Netherlands 12%, and Great Britain 11%. Traditionally, the applications of electronic microsystems became applications such as memories, displays and processors, as well as products which enabled the communication between various components or systems. In the last years, the miniaturization extended to fields such as cars, medical and household appliances. The expansion of systems to other sectors shall continue, having a more and more important connection with the nano-technologies and advanced manufacture technologies.

### **2.2.3. Bio-technologies**

These mean the use of microorganisms in the industrial processes of production of bio-materials, bio-fuels and, finally, the manufacture of textiles, leather and paper products. The bio-technology has the advantage of being environmentally-friendly, as it relies less upon the use of traditional energy resources, while it recycles what we usually call “waste”, which are raw materials for that industry. In the world classification of patents of bio-technologie, Europe is on the first place, followed at a small distance by Northern America, each with about 35% of the market, and then Asia 23%. In Europe, the patent market is dominated by countries such as Germany, Great Britain, France, and The Netherlands.

### **2.2.4. Advanced Materials**

These are the materials which have an internal structure enabling properties much enhanced than the traditional materials. Their importance is proved due to the special applications which they have in all the industries, and they help in the reduction of costs while increasing the performance, which means the increase of competitiveness. We should not omit their positive impact on the surrounding environment in comparison with the traditional products. The trend is to increase the number of applications for each newly discovered material by an average of 8, 6 applications per newly discovered material. The zones of applications cover the entire industrial spectrum: constructions, car industry, aviation, energy, medical,

automations, semiconductors, textiles, appliances and security. Europe represents about half of the patents for advanced materials, 30% Northern America, and 20% Eastern Asia. In Europe, Germany covers 50% of the patents, followed by France 14%, and Great Britain 10%.

### **2.2.5. Photonics**

These are defined as a branch of science and technology which uses the photons as carriers of energy and information, thus replacing step-by-step the role which belonged in the past to electrotechnics and electronics. Although it started in the 60s, the scientific foundations were placed by Einstein, who discovered that the light consists of elementary units which he called “quantum” and we call them photons. The development of electronics, of laser technologies, of optic fibres, enabled the creation of proper environment for the development of optical communications and the appearance of photonics, which combine subjects such as physics, nano-technologies, material science, bio-technology, chemistry, and electric engineering. The photonics is by excellence a „green” technology which enables the transport of energy without losses and the conversion of solar energy into other forms of energy. Interesting in this field is the fact that by 2001, Europe, Northern America and Eastern Asia were sharing equally the patent market. While Europe and Northern America remained with approximately equal percentages (29% Europe and 27% Northern America), Eastern Asia reached a quota of 42% of the total number of patents. The market potential of nano-technologies at the level of 2008 was of 150 billion dollars, and it is estimated for 2015 an amount of 3,100 billion dollars, which means an annual increase rate of 46%. With respect to the microsystems, in 2008 the market was of 250 billion dollars, with an estimate at the level of 2015 of 350 billion dollars, which means an increase of 13%; the bio-technologies are estimated to increase from 90 billion dollars \$ in 2008 to 150 billion dollars, with an increase rate of 9%; the market of advanced materials shall increase from 100 billion dollars in 2008 to 150 billion dollars, with an annual increase rate of 6%, and the photonics shall increase from 230 billion dollars in 2008, to 480 billion dollars in 2015, with an increase rate of 8%.

All the information above shows a very high potential of development for these technologies, with many potential applications at the stage of commercial testing or as concept which strongly interfere. Even if the increase rhythm indicates a potential risk as well, the market values prove that these risks are worth being taken. In addition to their market values, their use presents substantial advantages which means a low consumption of raw material and energy, the preservation of surrounding environment, a very wide range of applications, the use of highly qualified labour force, the creation of new business, the national development and, last but not least, the achievement of a high degree of satisfaction of the final users.

### **2.3. Role of “Key Enabling Technologies” In Configuring the Smart Fabrics Industry**

The textile industry, as it is traditionally known, is no more a profitable branch, in spite of huge investments, due to the high competition (Golra et al., 2011).

In order to face the strong competition, the entire manufacture process needs to be changed through the integration of technologies based on real time information. The concept of “smart manufacturing” was developed, which refers to the understanding and perceiving the reality in real time, and implies a rigorous planning and

coordination of the entire manufacture process. It integrates analyses of data based on advanced perceptions, under conditions of minimum consumption of materials and energy, and of maximizing the effects, which finally ensures the economic competitiveness of a country (Davis et al., 2012).

In order to outrun the current crisis and to create the conditions of economic development of a country, it is imposed the increase of investments in the process of innovation by intensifying the activity of research-development (Coccia, 2012).

The industry of smart textiles marks the beginning of a new industrial era by combining the traditional textile industry with other fields, such as IT, electronics, communications, design, where the research outcome in each individual field has impact on the creation of a new design of this industry. The central element is constituted by the individual with his needs of protection and defence, which are more and more satisfied by the integration of research in the above-mentioned fields with applicability in the areas of civil defence, military, medical monitoring, or location (Jayaraman et al., 2006).

The smart textiles originate in the field of chemical textile products which strongly developed starting from the 60s – 70s. In time, the technical materials were improved, but it was still considered that they fail to fully respond to the expectations. According to their usage, the technical textiles are classified into 12 categories (David Rigby Associates, 2010): agrotech (agriculture, horticulture, forestry), clothtech (technical components of footwear and clothes), hometech (components of furniture, household or floor coverage), medtech (hygiene and medicine), oekotech (environmental protection), protech (personal and property protection), builtech (constructions), geotech (geotextiles, civil constructions), indutech (filtration, industrial purification), mobiltech (cars, expeditions, railroads and air-spatial), pachtech (packaging), sportech (sport and leisure).

Currently, the way leads to the following level of transformation of the technical products as Jayaraman et al. (2006) show by the incorporation of sensors and microsystems inside the product or tissue. The new technology creates the concept of “smart clothing” and opens the way to new horizons of applicability. The research is directed towards a series of performance measurement parameters, by taking into account aspects related to costs, manufacture procedure, degree of ensuring the protection, the threat response.

The creation of “smart cloth” implies a hierarchic process (Bahadir et al., 2012) combining the textile materials with systems able to sense and generate response to the external stimuli (Spontak et al., 2009).

At each level there are elements making the clothes become more interactive, intelligent and ensure the information processing, by the integration of hardware and software (Bahadir et al., 2012).

Begrache et al. (2010) show in a study that the first projects associated with “smart cloth” were applied by American Army and NASA, which were involved in the creation of the equipment that could adapt to a hostile environment. The pioneer project was called MotherBoard, it was developed by Georgia Tech University for NASA, and it represents a suite that could detect the vital signs of the carrier, by means of integrated optic fibres. Starting from 1990 until nowadays, companies in Europe were intensively involved in the field of integrating the electronics into textiles. The current research in the field of smart textiles rely upon the integrated components conferring sensorial perception, “actuators” – monitoring of some

parameters, source of energy, data transfer, computer processing, connectivity, user interface (control and/or display).

As Jayaraman et al. (2006) show the fabrics used for “smart clothing” involve a structure of materials which allows it to be made according to the size of its carrier, to adapt to the conditions of land, to be pre-configured and re-configured according to the needs, to be resistant, comfortable when washed, easily wearable, to be easily decontaminated, easy to make and cheap. The fabrics should be lightweight, flexible, resistant, and to adapt to the shape desired upon manufacture; thus, they can be created of various elements, of newly discovered threads and fibres by new manufacture processes which allow their adaptability to the environment; they should allow the incorporation or attachment of various electronic devices.

The latest and most dynamic field of innovation with perspective of continuous development is incorporating the KET’s mentioned before and creating the “smart fabrics” considered as the industry of future, which shall use the most highly qualified labour force.

The European Competitiveness Report (2010) indicates the current applications of nano-technologies in the textile industry refer to the nano-particles for preventing the contamination, the silver nano-particles for antibacterial textiles and the nano-containers for the impregnation with certain flavours. There were recently launched materials with titanium oxides obtained by nano-technology for the protection against ultraviolet rays, nano-gels for the thermal protection and ceramic nano-particles for the resistance to abrasion. At the stage of research there are the textiles which have integrated the nano-sensors and actuators for controlling the operation of human body, and textiles which have integrated digital control nano-systems.

As a conclusion to the above, we could say that the borders of smart fabrics industry are actually provided by the technological borders in several fields which are in a permanent dynamics and interconnectivity.

#### **2.4. The Development of Business Environment in the Reconfiguration of the Textile Industry**

The appearance of new technologies determines the appearance of new standards of manufacture, innovation, creation, organization and delivery (Davis et al., 2012). In his study Jolly (2012) shows the way of organizing the industry determines the entry barriers. When a new technology becomes attractive and is the creator of a new business, there will be numerous companies interested in entering the market, due to a low entry barrier of the market, but also because each company will try to impose its own technical standard in the market. In time, the number of companies on the market in the respective field will increase, which means that the business is attractive. If any company succeeds in imposing their own design on the market, the other will have low chances of imposing their standards. The design imposed on the market refers to a certain technology implemented, which becomes attractive for many others. It means that there will be many companies on the market when there will be attraction for a certain technology. The selectivity criterion of a technology takes into account financial classic aspects, such as the recovery rate of investment, or cash-flow, the main objective being the maximization of potential income by risk unit. In general, the technological analysis envisages two aspects: its importance in the future – as a volume and life cycle – and the power it confers to the company as compared to the competitor companies. Another criterion of analysing the technology refers to its lifetime, which also incorporates the life cycle of the product.

A third criterion for selecting the technology refers directly to the mode of applying the patents: on the one hand, it reflects the attraction towards the respective technology by a high demand for that patent or, on the other hand, it shows the position of the company by applying the respective patent. There are situations when there was attraction from the companies towards a certain technology, but the products resulting from using it failed as there was no real demand from the customers existing on the market. Therefore, the commercial outcome is another important criterion in using the technology and thus, all the financial aspects derived from them (costs, benefits, value perceived by customer). In the case of entirely new technologies, it is difficult to estimate the potential the technology market is completely new. In this case, there is considered that as the technology is more attractive and covers the highest volume and depends on the geographical coverage, on the demand, the duration of usage, the range of applicability in various fields or in various market segments.

The location characteristics influence the activity of the companies involved in the field of nano-technologies are small or medium and are incorporated into a chain of value creation. Schimke et al. (2013) argue that these companies can only operate in regions with high degree of regional specialization, being the users of well-trained external labour force. There are situations when the regional specialization is counter-productive for the companies of nano-technology, as the level of qualification of the labour force is extremely important. Usually, the nano-technology is a creator of highly qualified labour force and the activity is carried out by clusters. Qing (2012) shows that most of the clusters have the support of local governments, which created favourable institutional environment and policies. By these measures, the entire arsenal of geographical, cultural, and business factors are valued thus ensuring the conditions for obtaining profit and creating new industrial branches besides those traditionally existing in the area, as well as the formation of specialized labour force and the increase of opening degree of the area, which should finally enable the attraction of capital and the intensification of entrepreneurial activity.

The entrepreneurial activity is a creator of economic development if it implies a high degree of innovation. As Lerner (2012) explains, the governments have the essential role of providing the conditions of a healthy entrepreneurial environment, which ensures the access of talents in a country by a flexible system of visas, enables the fluctuation of labour force between companies, provides the conditions of an efficient educational system for creating the future qualified labour force and finally, ensures the advantageous taxation policy. Also, the government has an essential role in providing the best conditions for dealing with the innovations, as well as in establishing clear rules of patent awarding. A modality of entering the market which is specific to the companies operating in the field of high technologies is presented in the form of the concept of "hybrid model", which combines the research activity in a laboratory and a start-up company sustained by an investment fund.

The development of business environment related to the smart textile industry depends on the creation of conditions for the investment by providing a friendly entrepreneurial environment, on the orientation of capital to the fields with high potential of development, which should use the highly qualified labour force, and on the type of technology implemented.

### 3. Conclusions

The traditional textile industry is in full transformation at the world level. The competitive disadvantages of some countries with respect to the cheap labour force and the supply of raw materials essential for this field can be compensated by the re-orientation to the configuration of a new model of industry, the one of smart textiles. And the main vectors in this effort of industrial transformation are the companies which are the best placed on the market of new industrial technologies generally called KETs, which combines the intensive use of capital with the sustained effort of research-development, the usage of highly qualified labour force, and their geographical positioning at the points which best respond to their operational requirements.

The advantages of creating and developing such an industry are the following:

- Low consumption of raw materials;
- Preservation of surrounding environment;
- Application of results in a wide range of fields with impact on the development of the entire economic environment;
- Usage of highly qualified labour force;
- Assumes the implication of Government in the creation of conditions for the development of a friendly business environment for the companies using the highest technologies, and the training and education of the labour force necessary for advancing in that direction;
- It means the future for a traditional industry;
- International cooperation in scientific matters.

All these will re-launch the economic activity passing through recession, particularly in the areas more prepared from the point of view of high qualification and technical specialization. And the Government is required to lay optimally the economic environment on coordinates favourable to such a process. This work responds to such challenges, by telling us how we could take benefit of this effervescence in the active areas of technical research, of the industrial and business development.

*catalinrusuzagar@gmail.com*

*sorinovidia@yahoo.com*

**Abstract:** *Health and safety at work has become one of the most substantial and important sectors in the EU social policy over the last years. In Romania, the implementation of health and safety management systems is performed by: a systematic approach to problems, training and awareness, effective and efficient tools for managing a company's specific issues as well as involvement at all its organizational levels. The article deals with the implementation of the management systems for health and safety at work, which complements the enterprises' existing organizational system and promotes enforcement of the legislation regarding health and safety at work. Creating a healthier and safer working environment is a goal that exceeds the resources and expertise of a single institution or a single country.*

**Keywords:** *management; security; health; work; best practices; prevention, awareness.*

**JEL classification:** *J28*

## 1. Introduction

Health and safety at work has become one of the most substantial and important sectors in the EU social policy over the recent years.

The European Community Strategy is based on setting up and reinforcing a culture of risk prevention, on combining a variety of tools for the implementation of the Community policies: legislation, social dialogue, technical progress and best practices, corporate social responsibility and economic incentives – and on building partnerships among all the actors on the stage of health and safety at work.

The Management systems for health and safety at work come in support of the implementation of the Community Strategy by:

- systematic approach of problems in the field;
- emphasis laid on training and awareness as important elements of culture concerning health and safety at work;
- creation of some effective and efficient management tools for managing the company's specific issues;
- involvement at all levels of an organization.

## 2. National Approach

The number of units that have already implemented the management systems for safety and health at work is still rather low, among the factors that have led to this situation we can mention:

- the short term to enact the mandatory requirement of implementing the system and quite a long time for completion;
- a shaping internal market in terms of the interest in health and safety at work;
- a very new and complex legislation in the field which still lacks the effective enforcement tools;
- a lack of tradition in global performance analysis on various business sectors/areas which could highlight the benefits of implementing the management systems;
- a poor flow of information.

The similarities between the EU directives and the elements of the management systems safety at work are presented in Table. 1.

**Table 1** Elements of the EU Directives and elements of the management system

<b>Elements of EU Directives</b>	<b>Elements of the management system</b>
Risk prevention	Emphasis on preventive actions
Empowering leadership at the highest level	Declared commitment management
Employees' awareness and training	Training - Awareness
Risk assessment	Risk assessment
Permanently decreasing the risks cannot be eliminated	Continuous improvement

Occupational health and safety management is the missing link in the development and implementation of integrated management systems: quality, environment, labor, according to the new European and international trends

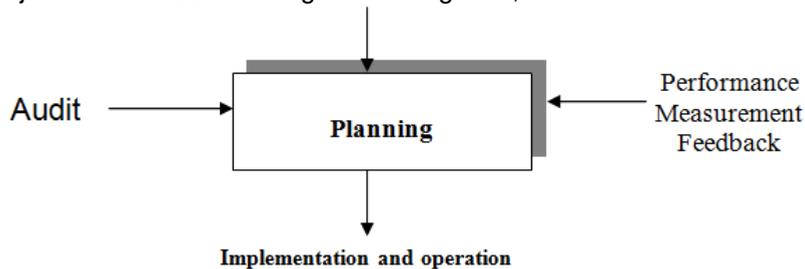

The implementation of management systems complements the existing organizational system within enterprises and promotes the regular application of health and safety at work legislation, integrating this area into the general management unit.

**Table 2** Approach of the work system elements within the management systems

<b>POLICY</b>	- observance of the permissible limits for the risk factors value = minimal objective
<b>PLANNING</b>	- objectives which are easy to quantify, pursue and verify; - direct reporting to vast, accessible secondary and tertiary legislation
<b>IMPLEMENTATION OPERATION</b>	- large number of records; - complex, specialized operational control ; - specific data (values of risk factors, calculation models and simulation) to establish measures for emergency response
<b>VERIFICATION OF CORRECTIVE ACTION</b>	-measurement possibilities according to approved methodologies; - inter-comparison of results.

The elements of the planning stage are:

- Hazard identification, risk assessment and risk control;
- Legal provisions and other requirements;
- Objectives and OSH management Programs;

**Figure 1: Planning**

### **3. Objectives and Program**

The objectives must be in accordance with the policy and commitment for continuous improvement. Setting goals and objectives can be achieved within the management team.

Objectives should be:

- specific
- measurable
- **accepted**
- **feasible**
- should be within the limits
- established, maintained and documented;
- consistent with the legal requirements and with other requirements of the organization; with the risks identified in the assessment; with the organization's technology; with the organization's financial possibilities
- consistent with the commitment to continual improvement expressed in the policy.

**The OSH Management Program (PSSM)** - is a process that turns long-term general commitments in a short and medium term action plan through general and specific objectives. OSH management program contains clear, measurable objectives, set in accordance with

- OHS policy;
- identified priorities;
- risk assessment results.

### **4. Organization of prevention and protection activities within companies**

Organization of prevention and protection activities is provided by the employer in the following ways:

- by the employer's assumption of the duties necessary to implement the measures stipulated by the Law no. 319/2006;
- by designating one or more workers to carry out activities of prevention and protection;
- by establishing an internal service for prevention and protection;
- by resorting to external services for prevention and protection.

The employer's assumption of conducting prevention and protection activities according to art. 16 HG 1425-2006 by designating one or more workers to carry out the prevention and protection activities and by establishing an internal service for prevention and protection or resorting to external prevention and protection services (7,8)

**Table 3** Prevention service type

No. of workers	Prevention service		Oservations
	internal	external	
1-9	Employer		*)
1-49	Employer / designated worker	Risk assessment specialist	
1-49	Designated worker	Risk assessment specialist	activities from Annex no.5 of H.G.1425/2006
50-149	Designated worker	Risk assessment specialist	activities from Annex no.5 of H.G.1425/2006
50-149	Designated worker		
Over 150	Designated worker		

\*) if the following conditions are met cumulatively:

- micro or small enterprises;
- the activities carried out within the company are not referred to in Annex 5 of HG nr.1425/2006;
- the risks identified may not generate accidents or professional diseases with serious, irreversible consequences, respectively death or disability;
- the employer carries out his/her professional activity effectively and regularly within the company/unit;
- the employer meets the minimum requirements for training in the field of health and safety at work, corresponding to a basic level at least (7,8).

Prevention and protection activities carried out within the enterprise and/or unit are:

1. identify the hazards and assess the risks;
2. develop and maintain the prevention and protection plan;
3. develop their own instructions for completing and/or enforcing the health and safety at work regulations taking into account the particularities of the unit/enterprise activity as well as those of the workplaces/positions;
4. propose the tasks and responsibilities in the field of health and safety at work, incurred by workers, according to the functions performed, which shall be recorded in the job description approved by the employer;
5. verify the knowledge and application of the measures provided in the prevention and protection plan by all workers , as well as of their duties and their responsibilities in the field of health and safety at work, set in the job description;
6. draw up the technical documentation necessary for informing and training the workers in field of health and safety at work;
7. develop themes for all the stages of training, establish appropriate periodicity for each job, provide information and training for workers in the field of health and safety

at work, and check knowledge and application of information received by the workers;

8. develop training-test program for the enterprise and /or unit;

9. ensure preparation of the action plan in the event of serious and imminent danger, and make sure that all employees are trained to apply it;

10. highlight specific and high risk areas;

11. determine areas requiring occupational health and safety signals, establishing appropriate signal type and location according to legal requirements;

12. record the trades and professions, provided by specific legislation, which require authorization in order to be practiced;

13. record the workstations that require additional medical examinations (2,3).

## **5. Competence, training and awareness**

Minimum requirements for training in health and safety at work

*The levels of training in the field of health and safety at work necessary to achieve adequate capacities and skills for performing prevention and protection activities are: basic, intermediate and higher level*

The minimum training requirements in the field of occupational health and safety at work for the *basic level* are: secondary education; a course in the field of health and safety at work, lasting at least 40 hours.

- The minimum training requirements in the field of occupational health and safety at work for the *intermediate level* are: technical secondary education, a course in the field of health and safety at work, lasting at least 80 hours.
- The minimum training requirements in the field of occupational health and safety at work for the *higher level* are: technical higher education; a course in the field of health and safety at work, lasting at least 80 hours, a postgraduate course in risk assessment, lasting at least 180 hours. (9,10)

## **6. Good prevention practices**

DuPont Principles - Good health and safety practices at work

- All injuries can be prevented;
- The management, from top level up to the frontline supervisors, is responsible in terms of injury prevention;
- Combined energy of all organizations is necessary to ensure continuous improvement and achieving excellence in the field of safety;
- All occupational exposures that could result in injury or occupational diseases can be controlled;
- Security is a condition related to the workplace;
- Recognition of the necessity to train employees in order to work safely;
- The management must audit the performance at the workplace in order to assess the success of the security program
- All deficiencies must be promptly addressed
- Security is a constituent part of each activity but security is, at the same time, a part of everyone's life.
- Security is a good deal
- Security should be integrated as an essential approach and personal value (2,5,11)

## 7. Conclusions

Occupational health and safety is at the forefront in the national social agenda, from both economic and humanitarian reasons.

Intellectual resources of an organization include all intangible values, knowledge-based that can be: described, measured, turned into value and developed in accordance with current business and future prospects. Human capital consists of elements such as knowledge, skills, abilities and work capacity including aspects of physical and psychological health.

The role of health and safety at work is essential to enhance the companies' competitiveness and productivity through the positive effects it produces: reduces the cost of accidents, incidents and occupational diseases and increases motivation. Accidents and professional diseases are an enormous burden on public and private welfare systems and require an integrated, coordinated and strategic answer, as well as cooperation of the key stakeholders in national policy making.

## WORLD TRADE ORGANIZATION – REFORM IT OR CHANGE IT?

**Sterian Maria Gabriela**

Romanian-American University, Bucharest, Romania

[steriangabriela@yahoo.com](mailto:steriangabriela@yahoo.com)

**Abstract:** *The failure of Doha Round is a serious step backward for the WTO and the multilateral trading system. Some analysts already discussed in their research about the round as being already closed and they propose the developing of a new program within the organization. WTO still remains a very important institution due to its proven role in encouraging states not to take protectionist measures during the recent economic crisis, but the global trade governance reform must reflect all the changes and realities. The transition is being made toward a more regionalized and preferential global trade and the emergence of strong developing countries shape the whole multilateral trade negotiations. The important growth rates in emerging countries are translated also in strong demand for representation in global trade governance.* **Objectives:** *This paper aims to underline the role of multilateralism as form of international cooperation, the link with global economic governance and what concerns academic community in terms of having a reform of it.* **Prior Work:** *It has been tried to emphasizing the concepts already developed by known researchers in the field.* **Approach:** *The approach is a more theoretic one done in a comparative manner with emphasis on results and future research. The critical method approach is done with qualitative results.* **Results:** *The key results are related to pros and cons of reforming the World Trade Organization, as well as presenting the criticisms and proposals for having a second World Trade Organization.* **Implications:** *The implications are varied in terms of studying the concepts and addresses researchers in the field, but also lecturers and students.* **Value:** *The main added value is the compared approach of the traditional WTO as it derived from General Agreement on Tariff and Trade and the proposal for a new one and its formal relationship with the global economic governance.*

**Keywords:** international trade, reform, legitimacy, Doha Round

**JEL classification:** F02, F13, F55, O19

### 1. Introduction

Like many other international organizations, World Trade Organization (WTO) is at crossroads in terms of ideas and problems. There is a noticeable imbalance between the dispute resolution mechanism and the provided platform for multilateral trade negotiations. While the existing rules, supported by a strong dispute resolution mechanism, have provided the platform to mitigating some effects of the economic crises, international negotiations haven't provided concrete results since 1990's. It became obvious that the old methods are no longer feasible and require completely new thinking about the organizational needs of WTO.

### 2. Criticism and Critics

Most current debates about WTO refer to the legitimacy and effectiveness of its decisions (Ziegler and Bonzon, 2007). The legitimacy problem is related to the

extended influence of WTO and, often, to state sovereignty. The consensual decision-making principle is one of the main subjects in WTO criticisms, being argued that they are made only at formal level and reflect the power relations between member states, in the form of a weighted vote according to major interests. The informal practices, which lead to adopting decisions, involve the emergence of groups with restricted composition that deliberately exclude other countries (Kim, 2009).

Consensual practices in the GATT/WTO has always meant that all parties have to agree upon a specific subject, but in practice this voting system could be a hidden one; reality proves that the share of the voting countries is more important than the one of the smaller countries (Low, 2011).

Much of the criticism results from the perception that trade liberalization have been raised to very high ranks, while other values were slaughtered. A proposed solution to this problem is to slow down or stop the expansion of WTO in areas not covered by trade with goods. But can WTO include non-trade issues within its agenda? WTO is the precursor of GATT and therefore is quite less equipped to consider other problems; skeptics say that we need another specialized organization to address these issues (Sun, 2011).

The isolationist approach of the WTO, as an independent legal island, ignores the wishes of its members, concludes agreements in their detriment, builds trade rules out of their concern and wishes to correct failures of environmental or social issues more than it can. We cannot speak of coordination and coherence as long as the WTO rules always prevail over other agreements (Pauwelyn, 2005). WTO should not hold a monopoly in international cooperation.

A lot of countries feel excluded or left behind by WTO rules and for the most of poor countries participation in the system remains a distant dream. Trade system has been perceived as a fortress by the outsiders, with discussions being held behind closed doors, the majority of decisions being in favor of strong and powerful producers and exporters; but also by the insiders, which are tied to commitments in "package" and with no way out, because of the economic realities or because of a strict implementation mechanism. Hence results the lack of legitimacy, poor support and lack of loyalty to the values that underline the system (Sutherland and al, 2004). WTO critics relate easily to the existing democratic deficit within the organization (Elsig, 2007). Unlike the early years of the GATT, the lack of organization's legitimacy is no longer offset by the progress towards trade liberalization. Cooperation under GATT in an anarchic era seemed easier than the one today, taking place in an environment governed by rules and procedures. WTO has fundamentally changed the nature, purpose and structure of the multilateral trading system. It became the target of lobby groups and civil society, which led to excessive politicization of the organization (Mercurio, 2007). Critics say that the big number of members doesn't allow the organization to reach consensus or to effectively address the problems in the 21<sup>st</sup> century, which leads to blockages and disagreements within negotiations (Sun, 2011).

### **3. The Failure of the Doha Round**

Trade liberalization was not an easy thing to be achieved over eight rounds of multilateral trade negotiations, but it has changed the world trade. It offered a bulwark against the evident protectionism of developing world, but also stability and growth, which led to avoiding trade conflicts (Sutherland, 2011). The disintegration of trade

negotiations and the continuous inability of the WTO to reach an agreement are worrying (Mercurio, 2007). The failure of the Doha Round is based on the misunderstandings among states and on the refusal to compromise.

But how did we get here? Two arguments are brought forward: ten years of negotiations have made some progress, but because of the blockages, the current negotiations will not be concluded in the next period; no government wants to announce publicly that it waives the negotiations (Baldwin and Evenett, 2011). This impasse would occur due to not achieving consensus on tariffs and market access in sensitive sectors, as a result of direct disapproval of the United States, China and India in July 2008 (Kim, 2009).

WTO has shown its importance in expanding trade opportunities and by creating a dispute settlement mechanism that imposes obligations and solves trade disputes among countries. It has brought tangible benefits to many developing countries, supporters say, and it was expected that the completion of Doha Round would provide substantial benefits and assistance for most of the least developed countries (Sun, 2011). But the emergent countries have adopted offensive positions because of their own interpretation of regulations to serve their interests. They have demanded negotiations on equal footing, claiming common approaches to global problems, but maintaining their status of developing countries.

Brazil, China, India and South Africa (G20) have asked free market access in developed countries, while having same resistance on their own market access. Japan, Switzerland and Norway (G10) maintained the negative attitude and the defensive approach in the negotiations regarding agriculture due to their lack of competitiveness at international level. Low income countries (G33), net food importers, focused on the following issues: special treatment, access to developed markets for agricultural products, reducing preferences (Mercurio, 2007).

A significant number of contributors have suggested that further negotiations should provide the necessary impetus by launching an effective program of work rather than continuing the process of negotiating on how WTO could address the problems of the 21<sup>st</sup> century, some of them already exceeding the initial Doha agenda from 2001. They have considered two ways: the first one considers the institutional reform of the WTO; the second one considers new issues, like the increased trade, investments and services convergence and the establishment of acceptable limits of national climate policies with trade implication (Baldwin and Evenett, 2011).

There are also intensely analyzes of the costs of Doha Round stalemate (Pangestu, 2011), the biggest one being related to food crisis and security. During the 2008 food crisis, the imbalances between supply and demand were attributed in part to distorted prices prevailed in agriculture, resulting in export subsidies and domestic support system. Removing these distortions can occur only if decisions are made at regional and bilateral level rather than at multilateral level.

Second of all, there are analyzes of the protectionism costs. Throughout the crisis, a moderate form of protectionism arose at the global level, which allowed the recovery of trade exchanges. The most used trade barriers were increased custom duties, licensing and export restrictions. Developing countries, such as Indonesia, are interested in reducing protectionism, given the assumption that multilateral trade system is fair for everyone.

Third of all, the lack of progress of the Doha Round remains a pressure on trade negotiations at bilateral and regional level. In the South-East Asia there are already regional agreements between ASEAN members and the six key partners (Australia,

China, India, Japan, South Korea and New Zealand), as well as bilateral free trade agreements. EU has bilateral agreements with South Korea, India and ongoing ones with Singapore, Malaysia and other ASEAN countries.

Fourth of all, there is an inhibitory effect in addressing unilateral reforms by the WTO members. The economic policy of trade liberalization and the institutional reforms have always worked better than international commitments have had. The multilateral rules and regulations have always imposed limits in states' decisions, being accepted only the beneficial ones.

Most analysts agree that negotiations should be continued and reaching compromises to achieve both new market access and market reforms (Schwab, 2011). One thing is clear: the basic structure of Doha Round is a combination of self-selected flexibility that hasn't work and won't work. It has led to the situation in which each part has to assume political costs of its own decisions, while waiting for the other parts to disagree with market access. Another element to be considered is the division of states into three basic categories (developed, developing and least developed), a practice that no longer fits the realities of the 21<sup>st</sup> century and provides no real progress in the negotiations. Developed countries will always have more to do than those in other stages of development, but expectations should reflect the fact that many emerging economies are shaped by poverty, even if they are globally competitive powers.

The adverse implications of a continued stalemate of Doha Round in the future of WTO are too convincing to be rejected (Bhatia, 2011). Global problems require international cooperation. Food security and energy, trade related aspects, labor mobility, price volatility, trade liberalization and integration are current issues on global agenda of any international negotiations. There are many analysts who believe that the WTO structure can withstand the failure of the Doha Round, but it should not be underestimated the changes that have taken place with the rules established in 1994 and based on the initial agenda of negotiations under GATT.

To announce that Doha Round has failed is a simple one, but what happens after? Will this strengthen the multilateral trading system? If WTO stands, this takes only to the new rules negotiated by its members. However, the failures registered in the last 10 years will not be deleted as soon as a new round starts. Another option would be giving up the previous negotiations in Doha Round and all WTO members agree upon the final package of rules and norms. This would allow the commissions to continue their activity, with new norms instead of old ones. But after 60 years of customary practices, will someone agree with common practices?

However, the failure of the G20 in strengthening the multilateral trade system by concluding Doha Round is a major cause of the lack of credibility. If developed countries will experience further slow economic growth, the effect is to introduce protectionist measures, even if WTO has imposed limits. The problem is that the excessive non-tariff measures applied over the existing tariff rules leaves room for interpretation in terms of protectionism.

But the current international political environment is not conducive for achieving consensus and complete multilateral trade talks. The economists argue that if there will be no impact on globalization, the Doha Round will not end (Frieden et al, 2012). If, however, the current problems leave room for trade talks, the Doha Round can be completed, leaving room for WTO to address other issues that are already a challenge for the multilateral trade system.

#### **4. Proposals for WTO Reform**

Those who support the reform of global economic governance go on equity and social justice, but also on economic justice through extending social problems at global level. The reform implies a radical revision of the normative foundations of global governance and calls for such arrangements in the global economy and international organizations (Kim, 2009). Global governance can be inconsistent with the criticism raised by WTO opponents (Guzman, 2004). What is clear is the fact that international cooperation provides an effective strategy to address the concerns of WTO reform.

For more than a decade, the WTO faces an existential crisis, continued by the unsuccessful conclusions of the Doha Round. Baldwin said that there are assumptions on the fact that the organization is on the brink (Baldwin, 2006). The raising number of regional agreements and informal institutions lead to the expansion of preferential agreements, increasing the protectionist sentiment in overcoming inefficiency about WTO decisions in its legitimacy crisis and the effectiveness of its objectives (McGrew, 2011).

In terms of decision-making process, most reform proposals relate to improving the WTO efficiency (Ziegler and Bonzon, 2007). Some researchers have proposed giving up consensual decisions and replacing it with the weighted voting system (Cottier and Takenoshita, 2003). Other suggests a fine adjustment to the consensus (Jackson, 2001). There are times when efficiency and legitimacy can collide; when raising efficiency implies formal moving from consensus to effective decision-making, the impact is negative for legitimacy in terms of the equality of sovereign states (Jackson, 2001). WTO reform has been analyzed extensively by researchers, and modifying the geometry of global economic order after shaking the concept of globalization have led to deepening of the existential crisis of WTO and to the need of shaping a new global economic governance. The financial crisis has created the opportunity to rethink the global order and its immediate recovery (Gamble, 2009).

Is there the possibility that the crisis of WTO exist for over a decade? The current economic environment contributes to the fact that WTO has entered into a decisive phase of its institutional development. The crisis of multilateralism was one of the decisive factors in shaping consensus on WTO existential crisis (Henderson, 2002). Both supporters and critics of WTO seem to share the view that multilateral economic governance and the consensual decision-making process are dysfunctional and ineffective; the decisions in deepening trade liberalization have been significantly reduced, dispute settlement mechanism is overestimated and the initial objectives are controversial. There are brought arguments in the direction of institutional reform and its consequences on WTO and its members, but the key question remains related to which direction should start the process (Kim, 2009).

In the context of WTO reform, the researchers do not aspire to the idea of a world government, but they plead for the transfer of sovereignty from to the national level to supranational level. They argue that the legitimacy will increase only by lowering the governance levels, and a great obstacle for legitimacy is the inadequate external accountability (Elsig, 2007). But the actual consensual decision-making process does not promote legitimacy. This can be improved by formalizing the practices in consensual decision-making and increase its transparency. There are proposals related to WTO activities through power distribution to smaller decision bodies, which

leads to a decreasing in legitimacy because they are underrepresented institutionally (Ziegler and Bonzon, 2007).

The WTO crisis is supported by the inconsistency of reform programs, with technocratic proposals of Sutherland and Warwick Commissions or with other radical ones. Here we face a paradox in the sense that the speeches on crisis have made possible the WTO reform and also offered the development of coalitions who oppose to the institutional reform agenda.

In 2004, WTO published Sutherland Report, with a comprehensive assessment of institutional failures faced by the organization in the early 21<sup>st</sup> century and offers a multitude of reforms, aimed mainly to improve institutional efficiency (Sutherland et al, 2004). The problems underlined in the report, the proposed solutions and how the report was drafted was considered a missed opportunity for WTO reform. The defensive position of the multilateral trading system has been in favor of supporting the WTO and has brought allegations which extended criticism (Pauwelyn, 2005).

The Sutherland Report has taken into account the coordination between WTO activity and other intergovernmental organizations, but it takes more than several international rules to avoid the failures of international market. It addresses the challenges of WTO dually, making a distinction between WTO policy and the regulatory and dispute settlement mechanism.

While detailed proposals have been offered and have covered most WTO operational areas, the Report focused more on the institutional design and on improving the negotiations and decision-making process. The Report has reflected many of current concerns about the crisis of multilateralism and has made several recommendations for continuing the nondiscriminatory principles in a variable geometry for decision-making process, in which smaller specialized groups replace the current negotiation mechanism (Wagner and Von Bogdandy, 2005).

Many critics of this Report have examined the proposals in comparison with their philosophical views about WTO reform. The Report has been being criticized for being narrow in approach and not providing an overview of international politics (Elsig, 2007).

In December 2007 it was launched the Report of Warwick Commission that analyzes how international trading system can effectively serve the global community (Warwick Commission, 2007). It have taken into account the changes of global economy in association with the emergence of new economic powers, with their growing aspirations, but also social and societal issues, that require the rethinking of the principles and practices that guide the multilateral trading system.

The findings of this Report have been optimistic and provided solutions for most of WTO issues.

The economic and financial crisis has led to numerous proposals of reform and criticism to the WTO activities. World Economic Forum has come in 2010 with proposals to WTO reform, stressing the importance of subsidiarity in decision-making process in order to minimize national autonomy. The proposed approach has been the one of "*club of clubs*" of countries to more effectively address current challenges. It is claimed supporting a program which completes all future agreements as being defined in the Uruguay Round, with additional commitments for only a part of the members willing to do it. But how is this possible?

The economists argue that WTO already works this way because it allows the existence of several plurilateral agreements under its aegis. The best example is the Agreement of Government Procurement established in Tokyo Round which provides

useful guidance for how these clubs should work. This approach leads to rules with much lower impact than those established at the multilateral level (Frieden et al, 2012). But this is not necessarily bad. Members are encouraged to join small clubs with fewer risks. This would call into effect the principle of reciprocity, fundamental in the dispute settlement mechanism. Because they represent independent agreements, these clubs will be willing to make concessions in order to have more members and WTO members will not feel that joining one club or another means the loss of currently benefits they enjoy under the WTO agreements.

There are also outlined the benefits of this reform proposal. Trade issues would be addressed on a much larger scale, as well as the rest of the topics directly related to those remained suspended in the latest round of multilateral negotiations. Members, who wish the deepening integration under the WTO, can do it successfully, not being required to consider that this thing would serve their own interests. These elements would strengthen the legitimacy of WTO and the interested ones can implement an agenda for deepening integration processes (Baldwin, 2012).

The approach "*club of clubs*" creates and concerns WTO critics. The first concern is related to that fact that WTO would be faced with two classes of countries, some of them belonging to a group, some of them not. Supporters say the division won't be so sharp, especially because there are already differences between states in terms of obligations. A second concern is that a small number of states will establish a specific pattern of their club, which is going to restrict the access of new members. The fact that Uruguay Round led members to accept and implement the agreements in Tokyo Round has been seen as a worrying precedent. But supporters believe that these clubs will become an intrinsic part of WTO and all members are going to be able to accept and implement further obligations (McGrew, 2011).

A third concern is that this approach could limit the ability of members to obtain agreements in their own interests. Supporters say that members will agree to assume certain obligations not just because they are beneficial, but also to sell them to get more in return. On long term, both sides will have benefits and, even there are fewer universal rules, the implemented ones will be supported by stakeholders. A final concern relates to the fact that the organization would greatly expand. Critics say that a major failure is to extend the Doha Round and that other issues than trade are better managed by OECD or IMF (Zürn, 2004).

WTO reform depends on the interest of the large global players, in essence the members of G20. Assuming that the main ingredients are complemented by basic WTO commitments, the approach "*club of clubs*" might contribute to a deeper global integration and alleviate the existing institutional tensions when it comes to WTO. It gives a compromise in which diversity can coexist with expanding commitments of member countries. Clubs might prove to be a support in promoting the central targets: lowering trade barriers, reducing discrimination based on domestic policies, strengthen the economic development through trade. This would enhance WTO legitimacy and ensure better alignment of targets and objectives, means and effectiveness of the international organization.

WTO centrality in global trade governance has eroded and continues in this matter, but multilateralism will continue to lead the international trade. But in terms of the most dynamic segment of international trade (supply chain), the debate is fragmented and even exclusionary (Baldwin, 2012). Without a conclusion to the Doha Round negotiations, WTO members have a significant stake in approaching this issue, which becomes more and more regionalized. The governance gap in this

area is partly covered with bilateral trade agreements, especially between United States, European Union and Japan, but also autonomous reforms applied by emerging countries, which means that WTO has no role in the emergence of norms and rules that are established regionally.

In terms of traditional trade, WTO is still the supreme authority. But the appearance of strong emerging countries and regional guidance of trade has already changed the governance of international trade. East Asia countries have launched their own initiatives, a trend that increases the fragmentation within the multilateral trading system. The economists say it is almost impossible to bring regional rules on global supply chain (Baldwin, 2012). And even if China and other BRICS countries will want to bring these discussions at the multilateral level, rules have to be negotiated under the umbrella of a multilateral institution; for this reason, WTO seems to be the best candidate just on the light of the fact that developed countries will want equal treatment regarding exporters, without preferential treatment for emerging countries. Eliminating preferential treatment is an essential part of the governance process of supply chains. But many WTO members are not involved in the global supply chain, which means that it will be very difficult to reach consensus at the multilateral level; only QUAD members (United States, European Union, Japan and Canada) have to reach consensus with emerging countries. Baldwin suggests the coexistence of two organizations in global trade governance:

**Table 1: WTO 1.0 versus WTO 2.0**

WTO 1.0	WTO 2.0
<ul style="list-style-type: none"> <li>• traditional organization</li> <li>• elimination of trade barriers</li> <li>• multilateral norms and rules</li> <li>• cover issues related to international trade and liberalization of goods</li> <li>• unlimited number of members</li> <li>• membership is a must</li> <li>• prisoner's dilemma</li> <li>• preferential treatments</li> <li>• win-win cooperation</li> <li>• existence of exemptions and special cases</li> <li>• problem with coordination</li> </ul>	<ul style="list-style-type: none"> <li>• new organization</li> <li>• providing global supply chain</li> <li>• bilateral and regional norms and rules</li> <li>• cover other issues on the agenda of multilateral trade negotiations</li> <li>• reduced number of members</li> <li>• membership is a luxury</li> <li>• resistance dilemma</li> <li>• without preferential treatments</li> <li>• win-lose cooperation</li> <li>• strict discipline in trade</li> <li>• coordination is a must</li> </ul>

## 5. Conclusions

The approach taken in this article represents a marked point of departure from much of the modern economic literature regarding WTO. In the latest 20 years, the economists sought to develop theoretical rationales for the WTO, and multilateral agreements have been really important in shaping trade relationships. However, the Doha Round has not been yet finished accordingly. There is a great need of research to understand why impasses can arise after a negotiation has begun with such high hopes. Further research is necessary for finding the best approach in terms of reforming the multilateral trade. WTO has to stay on track in the 21<sup>st</sup> century or to engage constructively in a new range of disciplines necessary to underpin 21<sup>st</sup> century trade.

## **A CROSS-COUNTRY ANALYSIS OF THE BANKS' FINANCIAL SOUNDNESS: THE CASE OF THE CEE-3 COUNTRIES**

**Şargu Alina Camelia, Roman Angela**

*Faculty of Economics and Business Administration, "Alexandru Ioan Cuza"  
University of Iasi, Romania*

*alina.sargu@feaa.uaic.ro*

*aboariu@uaic.ro*

*Abstract:* The European integration process has a direct impact on all the components of the macroeconomic environment. The existence of a well functioning and sound banking sector becomes of great importance for the integration process as the European Union economy is financed especially through this channel. The banking sectors of the new EU member countries have undergone through tremendous changes in the last decade, both from an ownership and also from a business strategy point of view, these changes having a direct impact on their financial soundness. Thus, the aim of our research is to empirically examine the financial soundness of the banks operating in Bulgaria, Czech Republic and Romania, three EU members countries from Central and Eastern Europe (CEE-3). In order to achieve this we have employed a combine quantitative analysis based on the CAMELS framework (namely Capital Adequacy, Asset quality, Management soundness, Earnings, Liquidity, Sensitivity to market risk) and the Z-score, thus being able to underline simultaneously the financial soundness and the possibility of default for the banks from our sample. The analysed period is 2004-2011 providing us with an evaluation of the impact that the EU ascension and also the global financial crisis had on the financial soundness of the analysed banks. Our sample is composed from 40 commercial banks that operate in Bulgaria, the Czech Republic and Romania, that overall own over 75% of the total banking assets, making this study one of the most comprehensive undertaken to this date. The data that we have employed in our research is obtained from the Bureau Van Dijk Bankscope database and the annual financial statements of the banks from our sample. The paper through its original dual approach contributes to the academic debate by providing not only insight into the financial soundness of the banks operating in the CEE-3 countries but also underling their financial strength through the usage of the Z-score. Thus, the topic of the paper is focused on a subject of great importance for the European integration process.

*Keywords:* integration, financial soundness, CAMELS framework, Z score

### **1. Introduction**

The recent global crisis, through its severe implications on the financial systems and the real economy, underlines the major importance that the evaluation of banking sector soundness has for the identification of the weak points and the vulnerable banks, being known that if the problems are identified late the solutions for solving

them are more costly and the risk that the vulnerabilities will spread in the whole banking system are greater.

To assess the soundness and stability of the banking system a wide range of tools is used, among which stands out especially the analysis of a set of quantitative indicators conceived by the IMF and World Bank (IMF and World Bank, 2005). In order to ensure the comparability of data at an international level, the IMF published in March 2006 a *Compilation Guide on Financial Soundness Indicators*. According to this publication, given the complex nature of the financial system and the interconnections between the financial system and the real economy, financial soundness indicators are divided into two groups, namely the first group (entitled the core set) composed of the main indicators of the banking sector, at which references our paper as well, and the second group (entitled encouraged set) composed of other indicators of the banking sector and also of a series of non-banking sector indicators.

The core financial soundness indicators refer to six key areas of banking activity resulting from the CAMELS framework (namely *Capital Adequacy, Asset quality, Management soundness, Earnings, Liquidity, Sensitivity to market risk*), considered one of the most popular methods of analysis and assessment of the financial soundness of banks.

The major importance that the assessment and analysis of the banking sector soundness has led central banks from a series of countries (like the Central Bank of the Turkey, The Swiss National Bank, Netherlands Central Bank, Czech National Bank) to intensify their concerns regarding the creation of an aggregate indicator of the soundness of the banking sector, based on the consideration that the banks are the most important component of the financial system in terms of financial stability (Geršl and Heřmánek, 2006).

In this context, the aim of our research is to examine the financial soundness of the banks operating in Bulgaria, Czech Republic and Romania, three EU members countries from Central and Eastern Europe (CEE-3). In order to achieve this we have employed a combine analysis based on the CAMELS framework and the Z-score thus being able to underline simultaneously the financial soundness and the possibility of default for the banks from our sample. The analysed period is 2004-2011 providing us with an overview of the impact that the EU ascension and the global crisis had on the stability of the analysed banks.

Our research is structured as follows: the second part provides a review of the academic literature on this theme, the third part presents the data and methodology used, the fourth part is dedicated to the analysis and discussion of the selected banks soundness and the fifth part contains the concluding remarks.

## 2. Literature review

The existence of a strong, solid and stable banking sector represents an extremely important element for all participants to the economic environment either depositors, investors or entrepreneurs especially in the case of the new EU member countries, in which case the economy is financed overwhelmingly through this channel. Taking these into account, the subject of the financial soundness and performances of the banking system has become, especially in the last period of time, the focus point of both public authorities and scholars.

One of the most used models for the estimation of a bank performance and financial soundness has been in the last years represented by the CAMELS framework (Baral, 2005). In practice this system has been used by the regulatory authorities as a bank supervision instrument (Gilbert et al, 2000; Hays et al, 2009) and also as a model for the evaluation of the performances registered by a banking institution (Derviz et Podpiera, 2008; Atikoğulları, 2009; Mishra et al., 2012). The popularity and robustness of this method is also underlined by the inclusion in the handbook for the evaluation of the IMF members banking sector financial soundness of the CAMELS framework (Sundararajan et al, 2002).

Also in the academic literature the CAMELS framework has been employed in order to estimate the soundness of various banking systems. Thus, Godlewski (2005) tests the validity of the CAMELS framework for banks defaults models in emerging markets. The results confirm that the indicators for bank solvability, assets quality, liquidity, management quality and profitability have a negative impact on the probability of banks default. Brossard et al. (2007) estimate an early warning model for banks failure using the CAMELS framework for a panel of 82 EU banks for the period 1991-2005. The obtained results underline that a measure of past average growth of assets can be a very good predictor for future possible banks difficulties. Wang (2012) explores the relationship between the operating performance and corporate governance of bank holding companies in the United States of America. The results underline the positive link between corporate governance and the improvement of the financial soundness indicators from the CAMELS framework.

In recent years another indicator, namely the Z-score, has become a rather popular indicator for the underling of the financial soundness for banking institutions in various researches (Hesse et Čihák, 2007; Beck et al., 2012; Borgioli, 2013). The main reason for this evolution is that the Z-score enables an easy and direct way to interpret the financial soundness of a banking institution, underling the ability of a bank to face risk with the capital and profit buffers that the banking institution has. The research of Stiroh (2004) assesses potential diversification benefits for the US banks that have steadily increased their reliance to non-traditional business activities. The results imply that the move toward noninterest income is actually worsening the risk/return trade-off measured with the help of the Z score for the typical bank, as volatility increases while average returns decrease. Mercieca et al. (2007) investigate whether the observed shift into non-interest income activities improves the performance of small European banking institutions, employing for this a sample of 755 small banks over the period 1997–2003. The negative correlation between the Z score and the diversification of the small banking institutions underline that European small banks are entering market niches on which they have no expertise and implicitly the risks tend to increase rather than decrease.

Despite all these, the number of studies focused on the new EU member countries that employ the CAMELS framework or the Z score, or both methods, in order to underline the financial soundness of the banking institutions that operate in these countries is rather small (e.g. Ivičić, 2008; Albuлесcu et Coroiu, 2009; Dardac et Moinescu, 2009). Thus, our research intends to fill this gap by providing an analysis of the financial soundness for the Bulgarian, Czech Republic and Romanian banking sector in the EU ascension and financial crisis period, employing a dual approach based on the CAMELS framework and the Z score.

### 3. Data and methodology

Our sample is composed from 40 commercial banks, 11 from Bulgaria (owning 69,95% of total assets), 14 from the Czech Republic (owning 85,58% of total assets) and 15 from Romania (owning 78.10% of total assets). The data that we have employed in our research is obtained from the Bureau Van Dijk Bankscope database and the annual financial statements of the banks from our sample.

We have calculated the average individually for each of the indicators and parameters of the CAMELS framework for the period 2004-2011 (see table 1). The obtained results have been used to rank the banks, rank one being attributed to the best performing banking institution the rest of the banks being ranked accordingly, using a step of one. In the case in which we have obtained the same average for two banks we have attributed to those banks the average of their ranks. Averaging the ranked obtained for the different components of the CAMELS framework we have estimated the financial soundness of the commercial banks from our sample.

In order to estimate the *capital adequacy* of the banks from our sample we have employed two indicators. The first is the *total capital ratio* that reflects the ability of a bank to meet the time liabilities and other risks such as credit risks or operational risks. Generally there is a statutory level for the banks regarding this indicator, currently being at 10% for the banks operating in Romania, 8% in the case of the Czech Republic and 12% for the banks operating in Bulgaria. The highest rank is attributed to the bank that has registered the highest score for this indicator. The second indicator used is represented by the *ratio of the equity to total assets*. This indicator measures the proportion of the total assets that are financed by the shareholders of the banks, implicitly the highest rank being attributed to the bank that has registered the highest level for this indicator.

For the *assets quality* we have used three indicators, namely the *loan loss provisions to net interest revenues* ratio, the *impaired loans to gross loans* ratio and the *total loans to total assets* ratio. The *loan loss provisions to net interest revenues* underlines the ability of a bank to cover the expenses with the provisions for impaired loans from the interest that it collects, thus the lower the value of this indicator the higher the rank. The *impaired loans to gross loans* ratio underlines the ability of a bank to grant loans to prime clients that will repay their debts. Thus, the lower this ratio the better the quality of the loans portfolio and the banks will reach a higher rank. The ratio of *total loans to total assets* underlines how diversified is the activity that a banking institution undertakes. Despite being an important part of the total assets, if their ratio to total assets is high this exposes the bank to loans losses, thus the lower the value for this indicator the higher the ranked attributed.

In order to assess the *management quality* of the analysed banks we have used two indicators, namely the *operating expenses to total assets* and the *interest expenses to deposits*. The *operating expenses to total assets* ratio underlines the ability of the management to operate the daily activities of the banks at a lower cost, implicitly the bank with the lowest level of this indicator being ranked first. The interest expenses to deposits emphasis the ability of a bank to attract deposits at a low cost, thus the highest rank is attributed to the bank with the lowest score.

The earnings abilities of the banks from our sample are underlined by three indicators: the *cost to income ratio*, *ROA* and *ROE*. The cost to income ratio is obtained by dividing the operational costs to operational incomes and underlines how efficiently the bank is being run, implicitly the lower this ratio the more profitable the bank will be. Return on Assets (ROA) and Return on Equity (ROE) underline how

profitable are the bank assets / equity in generating revenues. Thus, the higher these indicators, the higher that bank will be placed in our rankings.

The *liquidity* of the banking institutions from our sample is underlined by their *liquid assets to deposits* ratio and the *net loans to deposits* ratio. The *liquid assets to deposits* ratio underlines the ability of a bank to withstand a possible bank-run, the higher this indicator the more secure that banking institution is, thus the highest rank is attributed to the bank with the highest score for this indicator. *Net loans to deposits* ratio underlines the ability of a bank to fund its activity from the attracted deposits. If this indicator is above 1 that the bank is close to become insolvent, thus the lower the score obtained the higher the rank achieved.

In order to underline the *size of the assets* that a bank has we have calculated the ratio of its *assets to the total assets of the banking sector*. Thus, the higher this ratio the more important is the bank for that given banking sector and the higher the rank achieved.

Alongside the CAMELS framework we have employed also the *Z-score* in our research, which determines the distance to insolvency for a bank (Roy, 1952) and is computed using the formula:

$$Z - \text{score} = \frac{\text{ROA} + (E/A)}{\sigma(\text{ROA})} \quad (1)$$

where ROA represents the return on assets, E/A is the ratio of total equity to total assets and  $\sigma$ ROA is the standard deviation of the return on assets. We have used as the denominator the standard deviation of the return on assets as we did not wanted to allow the Z-score to be exclusively driven by the variation of the capitals or the profitability. The Z-score can be interpreted as the number of standard deviation by which the returns on assets must fall from the mean in order to consume all the equity that a bank has and implicitly produce its bankruptcy (Boyd and Runkle, 1993). Thus, the higher the Z-score, the less that banking institution is likely to go bankrupt.

**Table 1: Summary statistics for the banks data used in our research for the period 2004-2011**

Indicators	Bulgaria		Czech Rep.		Romania	
	Avg.	St. dev.	Avg.	St. dev.	Avg.	St. dev.
<b>C</b> Total Capital Ratio	18.24	11.28	23.12	19.44	18.09	6.61

Source: Authors calculations based on Bureau Van Dijk Bankscope database (<https://bankscope2.bvdep.com>)

The banks operating in the Czech Republic are registering the best performances

in the case of the *capital adequacy* indicator, this being attributed to the more stricter approach that has been imposed by the national regulatory authorities in the aftermath 1999 banking crisis. The banks operating in Romania and Bulgaria are registering similar performances, that are however well above the minimal requirements imposed in these countries for banks capital adequacy ratios.

In the case of the *assets quality* indicators we can observe again that the Czech Republic banks have registered the best performances. By contrast, the Romanian banks have registered the highest impaired loans to gross loans ratio and loan loss provisions to net interest revenues ratio as a result of the high deterioration of the Romanian macroeconomic environment that took place once the financial global crisis has started. It is worth mentioning also that the Bulgarian banks are registering the highest ratio of total loans to total assets, making them extremely vulnerable to the evolution of the non-performing loans.

The *management quality* indicators provide an overview of the superior capabilities of the Czech banks to organise their daily operations in an efficient and impactful manner. The banks operating in Romania are registering the lowest performances, mainly because of the late privatisation of the largest bank in the system, Banca Comercială Română, in 2006. Another reason for the poor performance is represented by the high level of interest to deposits that the Romanian banks had to pay, especially in the aftermath of the global financial crisis in order to be able to attract sufficient liquidity from the market and thus comply with the new prudential requirements imposed by the National Bank.

The indicators for *earnings and profitability* underline the advantage that exists for the banks operating in Bulgaria that have to pay an income tax of only 10%. Also, the cost to income ratio underlines the ability of the Czech banks to operate at a lower cost than their Bulgarian and Romanian peers, especially taking into account the high income tax of 15% that they must pay.

The *liquidity* indicators suggest a split situation between the banks operating in the three countries. Thus, on the one hand the Bulgarian banks are the most liquid ones, while the banks from Romania are registering the lowest value for the ratio of net loans to deposits and short term funding, this underling the ability of these banks to completely cover their granted loans from the deposits attracted, making them the less probable to default in the case of a bank run.

In the case of the *size of the assets* indicator, the results registered in the case of the bank operating in the Czech Republic underline the high level of concentration that this banking sector has. The high standard deviation also points out to the high discrepancy that exists between the larger banks and the smaller one. A similar situation is registered also in the case of the Bulgarian and Romania.

#### **4. Empirical results**

The obtained results in the case of the banks operating in Bulgaria for the CAMELS framework are displayed in table 2. In this case the top five ranked banks are UniCredit Bulbank, Raiffeisenbank, DSK Bank, Corporate Commercial Bank and United Bulgaria Bank. We must underline that the biggest bank in Bulgaria, UniCredit Bulbank, has managed not only to be ranked first in the CAMELS framework but also has obtained the best ranked for the management quality. On the other hand the lowest five ranked banks are: Allianz Bank Bulgaria, Societe General Expressbank, First Investment Bank, MKB Unionbank and Procredit Bank. Allianz Bank Bulgaria,

MKB Unionbank and Procredit Bank are also the smallest banks from our sample in the case of Bulgaria.

**Table 2: Ranking of the Bulgarian banks based on the CAMELS framework**

	<b>C</b>	<b>A</b>	<b>M</b>	<b>E</b>	<b>L</b>	<b>S</b>	<b>Avg.</b>	<b>Rank</b>
<b>Allianz Bank Bulgaria</b>	10.5	2	6	8	2	8	6.08	<b>7</b>

<b>United Bulgaria Bank</b>	4.5	11	3	3	8.5	3	5.50	<b>5</b>

*Source: Authors calculations*

For the banks operating in the Czech Republic the results for the CAMELS analysis are presented in table 3. We can observe that the best results have been achieved by: Stavební Sporitelna České Sporitelny, Ceskoslovenska Obchodni Banka, Komerčni Banka, PPF banka and Ceska Sporitelna. It is worth mentioning that the biggest three banks by assets, namely: Stavební Sporitelna České Sporitelny, Ceskoslovenska Obchodni Banka and Ceska Sporitelna are also in the top five ranked banks. By contrast, the lowest four ranked banks are: GE Money Bank, Czech Export Bank, Equa Bank and Modra Pyramida Stavebni Sporitelna. Also in this case, except GE Money Bank, the lowest rank has been obtained by some of the smallest banks from our Czech Republic sample.

**Table 3: Ranking of the Czech banks based on the CAMELS framework**

	<b>C</b>	<b>A</b>	<b>M</b>	<b>E</b>	<b>L</b>	<b>S</b>	<b>Avg.</b>	<b>Rank</b>
<b>Ceska Sporitelna</b>	11.5	6.5	5.5	4.5	10	2	6.67	<b>5</b>
<b>Ceskomoravska Stavebni</b>	13	4	5.5	7	13	5	7.92	<b>8.50</b>

Table 4 displays the results obtained in the case of Romanian banks for the CAMELS framework. The top five banks ranked are: **RBS Bank, Raiffeisen Bank România, CEC Bank, Banca Comercială Română and UniCredit Țiriac**. In the case of RBS bank we must underline that, despite being a small bank, it has obtained the best ranking also in the case of assets quality, management quality and liquidity. The bottom five ranked banks are Piraeus Bank, Banca Comercială Carpatica, MKB Romexterra and ProCredit Bank, that are the smallest banks from our sample in the case of Romania.

Table 4: Ranking of the Romanian banks based on the CAMELS framework

	C	A	M	E	L	S	Avg.	Rank
<b>Alpha Bank</b>	11	10	4	5.5	7.5	7	7.50	<b>8</b>
<b>Banca Carpatica</b>	8.5	12.5	13.5	11.5	3.5	13	10.42	<b>13</b>
<b>Banca Comercială Română</b>	8.5	13	2	2	9.5	1	6.00	<b>4</b>
<b>Banca Românească</b>	4	4	11	10	12.5	10	8.58	<b>9</b>
<b>Banca Transilvania</b>	15	8	10	3.5	12.5	5	9.00	<b>10</b>
<b>Bancpost</b>	6	9	6.5	11.5	3.5	8	7.42	<b>6.50</b>
<b>BRD-GSG</b>	14	12.5	4	1	11	2	7.42	<b>6.50</b>
<b>CEC Bank</b>	5	2	6.5	9	6	6	5.75	<b>3</b>
<b>MKB Romexterra</b>	8.5	14	12	14.5	5	14	11.33	<b>14</b>

<b>UniCredit Țiriac</b>	8.5	6.5	4	7	9.5	4	6.58	<b>5</b>

Source: Authors calculations

In order to have a better overview of the financial soundness and to underline the probability for bankruptcy for the banks from our sample we have used also the Z-score. Analysing the results displayed in table 5 we can draw two quick conclusions. On the one hand, during the analysed period of time the banks operating in the Czech Republic have registered a slightly higher Z score than their Bulgarian and Romanian peers. The registered differences in the case of the Z score can be attributed to the low standard deviation of the returns on average assets registered by the banks operating in the Czech Republic. This is mainly because at the end of the 1990 the Czech Republic banking sector has undergone through a severe crisis, thus banks reorganising their operations and acquiring assets that produce steady incomes rather than high volatile returns.

Table 5: Z-score average decomposition for the banks from the analysed countries for the period 2004-2011

Country	Bulgaria	Czech Republic	Romania
Z-score	20,04	36,19	12,78
ROAA in %	1,76	1,12	0,77
Equity/Assets (in %)	14,01	11,60	10,94
Standard deviation of ROAA (in %)	0,84	0,42	1,30

**Source: Authors calculations based on Bureau Van Dijk Bankscope database (<https://bankscope2.bvdep.com>)**

Second, we can observe that the highest ROAA is registered in the case of the Bulgarian banks followed by the Czech Republic and Romanian ones. This is in line with the income taxes that exist, namely 10% in Bulgaria, 15% in the Czech Republic and 16% in Romania. Also the Czech banks have benefited from a more steady return on assets thus, registering a higher average compared with the Romanian ones, despite the small difference in the income tax level (1% point).

## **5. Conclusion**

The research undertaken has been focused on a sample of 40 commercial banks that operate in the CEE-3 countries, having an original dual approach and underling both their financial soundness and ability not to go bankrupt, thus the paper implicitly having a high level of added-value.

Pooling together all the obtained results, several conclusions can be drawn. First, in the case of the best ranked bank we can observe that the subsidiaries of large pan-European banking groups, especially Austrian ones like Erste and Raiffeisen, are present in the case of all the analysed countries. This can be attributed to the organisational and management strategy of these groups that are extremely focused on achieving a high level of financial soundness for all their subsidiaries. Second, we can observe that also in the top five ranked banks there are some domestic banks in the case of each CEE-3 countries, this underling that local knowledge and networking can provide these banks with the resources needed in order to have a very stable financial position. Third, we can observe that in the case of the lowest rated banks most of the time these are represented by the smallest banks from the sample for the analysed country. This is happening especially because these banks are involved in universal banking activities and have a high level of cost to customer ratio, while also any negative variation of their assets has a direct negative impact on their financial soundness indicators.

However, overall taking into account the results of the CAMELS framework and also the Z-score results we are able to conclude that the commercial banks operating in CEE-3 countries are registering a stable financial situation, the European integration process having a positive impact on their performances. This conclusion is in line with other studies on this topic from the academic literature (e.g. Ivičić, 2008). Also, in future researches it will be of interest to identify and analyse the factors that influence the evolution of the financial soundness indicators through a multiple regression analysis.

**Abstract:** *The paper aims at analysing the labour market, one of the most complex forms of market in economy. The present work forwards a comparative survey regarding the labour market in Romania and in the other European Union member states. The paper starts by highlighting general aspects related to labour market and continues by the presentation of the European Union countries' ranking according to the labour market efficiency, top elaborated on the basis of the World Economic Forum data. Furthermore, the paper analyses labour productiveness, employment rate and unemployment rate both in Romania and in the other countries of the European Union. In the end the authors forward conclusions regarding the possibilities of increasing competitiveness on Romania's labour market.*

**Keywords:** labour market; labour force; productiveness

**JEL classification:** J01, J21, J24

### 1. Theoretical Background

It is known worldwide that human resources are a crucial element in any country's economy, as it is recognised that labour force is a determining pillar of economic growth, an essential element of competitiveness and hence of economic development.

The triad physical capital - human capital - technological progress is essential for the development of any economy.

In this context, human resources represent "the key to increasing a country's global competitiveness and thus to realizing long-term economic success" (**Arcelus and Doran, 2003**).

The concept of human capital started to gain recognisance in the economic literature in 1961, along with the publication, in *The American Economic Review*, of Theodore W. Schultz's article entitled "Investment in Human Capital", where human capital was treated similarly with the physical capital (Schultz, 1961: 1-17).

There are numerous preoccupations in the economic literature related to the comprehension of the role of human capital in economic activity, among which we

must cite the remarkable contributions of R. Mincer, William Petty, Adam Smith, J. S. Mill, Alfred Marshall, Karl Marx etc. (Mirela Minică, 2005: 9-12.)

Among the promoters interested in studying human capital we can also mention Gary S. Becker (1994: 52-64), who defines this concept as “the monetary and non monetary activities influencing future monetary revenues”. These activities include school education, professional training during work, medical expenditure, migration, search for information about prices and revenues.

In this context, *labour market represents one of the most complex forms of market existing in economy, as it represents the economic space where the traded factor is labour*, and, according to Vogel (2003: 349-372), *labour market represents the main arena where the individual living conditions are determined*.

Efficiency and flexibility on labour market are critical for any economy, and consequently the intention is that the population fit for work fills positions and finds jobs so that the most efficient use in economy can be reached. Moreover, human resources should be stimulated in order to yield the best efficiency at the place of work (WEF, 2011:5).

## **2. Comparative survey regarding labour market in Romania and the European Union**

As regards labour market efficiency, *Romania ranks 23<sup>rd</sup> in the top of EU member states* (table 1), whereas *UK and Denmark* are still first and second (however, one year ago, their ranking was the other way around).

In 2012, *UK* improved its situation related to economic competitiveness, first of all grace to the increase of the labour market efficiency.

In this respect, in *UK* what is important is the co-operation relation between employer and employee, flexibility in setting the salaries, as well as the employment and laying-off practices. Furthermore, in *UK* they lay a remarkable stress on professional management, on the close correlation between employees' remuneration and labour productiveness, on the attraction of highly qualified labour force, etc. (WEF, 2013: 468-475).

On the other hand, Denmark has a unique specific labour market and still singles out as one of the most efficient labour markets in the world, with more flexibility in setting salaries or laying-off policies and thus with a higher employment capacity than in the other European countries. (WEF, 2011:23).

If in other countries, the aspects related to labour market are regulated by a series of laws, more or less adapted to the market requirements, in Denmark, based on the existing legal norms, employers and trade unions assume together the responsibility for most aspects related to labour market. This dialogue secures civilised relations, high salaries and special labour conditions. Denmark has practically the most flexible labour market in Europe.

Moreover, Denmark reports the highest number of employees and unemployed persons attending training courses.

In Romania, *labour market operation is hindered by the existence, still largely spread, of black labour or moonlighting, by the filling of different positions based on criteria different from those of value, by labour force emigration, by the problems occurred in the employee-employer relation, by the existence of a contested legislation in the field etc.*

**Table 1:** Index of labour force efficiency in the European Union countries

Country	Labour market efficiency	
	Rank	Points
UK	1	5.42
Denmark	2	5.22
Estonia	3	5.11
Finland	4	5.00
Ireland	5	5.00
Netherland	6	4.99
Sweden	7	4.81
Latvia	8	4.78
Austria	9	4.69
Luxembourg	10	4.66
Cyprus	11	4.57
Belgium	12	4.54
Bulgaria	13	4.54
Germany	14	4.51
Poland	15	4.48
France	16	4.41
Czech Republic	17	4.32

Malta	21	4.14
Lithuania	22	4.11
Romania	23	4.01
Spain	24	3.98
Portugal	25	3.80
Italy	26	3.72
Greece	27	3.56

Source: Elaborated by the authors based on the data from World Economic Forum, *The Global Competitiveness Report 2012 – 2013*, pp. 18-19.

*Note: These points are calculated by the World Economic Forum based on the statistic data or data collected with the help of surveys. In the case of surveys, the answers to questions were placed on a scale from 1 to 7 (1 corresponds to the lowest score, whereas 7 corresponds to the highest score). For each question, the individual answers are aggregated on the country level, in order to obtain the score of the respective country. On the other hand, the data from statistic sources are standardised for the same range [1, 7].*

Excessive taxation in Romania makes many firms operate outside the legal norms, which results in many employees working without a contract and consequently they cannot benefit from the diverse types of insurance and social security.

The fiscal pressure on the low-income employees was 43.8% in 2011, our country's figures being exceeded, in this respect, only by Belgium (49.7%), Germany (45.6%), France (46.5%), Italy (44.5%), Hungary (45.2%). (Eurostat, 2012: 258).

In the EU countries there are discrepancies also as regards the *labour force cost per hour (in industry and services)*. For instance, in 2007 it was 3.40 euros in Romania, higher only than the level registered in Bulgaria (1.89 euros). The highest labour force cost per hour is recorded in Denmark (34.74 euros), closely followed by Sweden (33.30 euros), Luxembourg (33 euros, and 33.63 in 2008) Belgium (32.56 euros, and 33.66 in 2008) and France (31.06, and 31.78 in 2008). (Eurostat, 2012: 259).

In Latvia, Lithuania, Slovakia and Estonia, in 2007, the labour force cost per hour was ranging between 4.40 euros and 6.60 euros, whereas in Poland, Malta and the Czech Republic it was ranging from 6.70 euros to 8.20 euros.

Although on a much lower level than in the European Union countries (except Bulgaria), in Romania “*the increase of labour force cost is much more substantial than in the EU countries, which is only natural in the process of bridging the gap to reach the level of salary incomes in the EU, but this fact translates also in the progressive loss of the comparative advantage of cheap labour force*” (Cojanu et al. 2007: 41).

Thus, even if the minimum salary has increased in these past years (in 2006 it was around 90 euros), in the first semester of 2013, according to Eurostat (2012), the minimum salary in *Romania* was 157.26 euros, the lowest in the EU, whereas the highest minimum salary is paid in Luxembourg (1874.19 euros). Thus, according to the level of the minimum guaranteed salary, the EU member states can be classified in three categories (table 2).

**Table 2:** Minimum salary in EU countries in the 1<sup>st</sup> semester of 2013

<b>Under 300 euros</b>	<b>Between 300 and 800 euros</b>	<b>Above 800 euros</b>
Romania (157.26 euros) Bulgaria (158.50 euros) Lithuania (289.62 euros) Latvia (287.07 euros)	Czech Republic (312.01 euros) Estonia (320 euros) Slovakia (337.70 euros) Hungary (340.55 euros) Poland (376.58 euros) Portugal (565.83 euros) Greece (683.76 euros) Malta (697.42 euros) Spain (752.85 euros) Slovenia (783.66 euros)	UK (1264.25 euros) France (1430.22 euros) Ireland (1461.85 euros) Netherlands (1469.40 euros) Belgium (1472.42 euros) Luxembourg (1874.19 euros)

Source: Elaborated by the authors based on the Eurostat data (2012)

Note: For the other EU countries there are no data available.

However, we must take into account that in view of growing economic efficiency, the index of salary growth must be lower than the index of labour productiveness. .

In 2011, in *Romania*, *labour productiveness per employee* was 49.4%, (figure 1) of the European Union average, higher only than in Bulgaria (44.0%).

The highest labour productiveness (above the EU average) was recorded in Luxembourg (169.1%). Labour productiveness per employee was higher than the EU average in other countries also, the highest percentages being registered in

Ireland (139.8%), Belgium (127.7%), Austria (116.8%), France (116.7%), Sweden (115.8%) - Eurostat (2012).

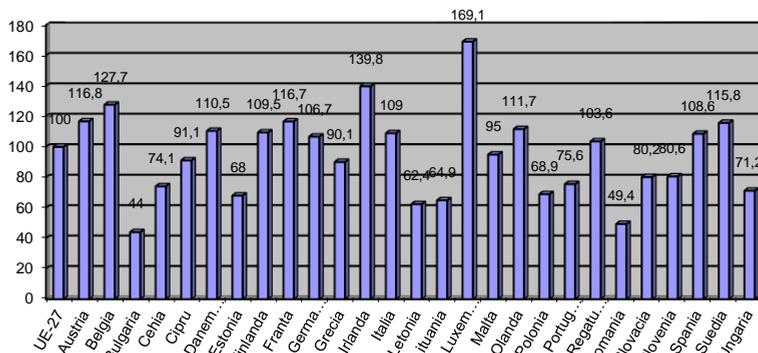

Figure 1: Labour productiveness per employee (2011)

Source: Elaborated by the authors based on the Eurostat data (2012)

Note: Greece – provisional data

As for labour productiveness per worked hour (EU-27 = 100), the highest values were recorded in Luxembourg (184%), The Netherlands (133.5%), France (130.6%), Ireland (128.2%), Germany (125.2%) – figure 2.

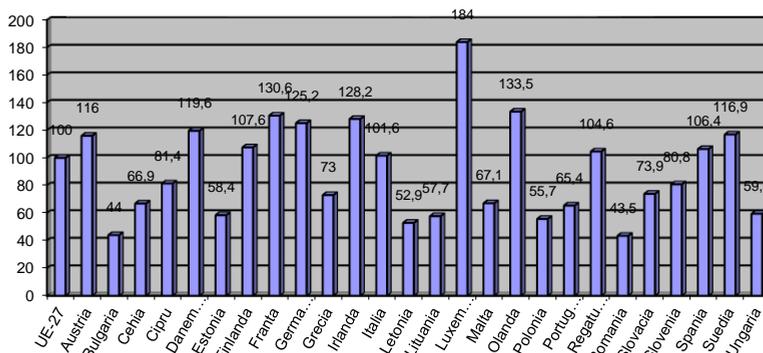

Figure 2: Labour productiveness per worked hour (2011)

Source: Elaborated by the authors based on the Eurostat data (2012)

Note: Greece and Portugal – provisional data

Belgium: no data available

The gap between our country and the EU-27 average is also apparent as regards the percentage of employed population per sectors of economy. Whereas in the European Union, in 2009, the percentage of persons employed in agriculture was only 5.1% (of total employed population), in Romania it was 29.1%. In industry, the percentage of employed population was 18% in EU-27 and 30% in Romania. On the other hand, in EU-27, more than two thirds of the employees are employed in services (67.3%), compared to only 40.9% in our country (NIS, 2010).

The high percentage of the population employed in agriculture, corroborated with the low percentage of people employed in services reflects not only the misbalances on

the labour market, but also the general inefficiency of economic activities in our country.

The fact that Romania joined the European Union had a powerful influence on its labour market, which became a component of the EU community labour market. This led to a higher mobility of labour force. Although the labour force flow is still limited by a series of regulation compared to the flow of products, services or capital (Marelli, 2006: 16-48) *in Romania, emigration has exhibited an ascendant trend, due to the better labour conditions and, first of all, due to higher wages in the other EU community countries, with negative effects in certain fields of activity confronted with a labour force deficit.*

Moreover, *Romania* is also confronted with a decline in the domain of labour force because of the *demographic stagnation and general population's ageing*, situation encountered in other states of Central Europe also, characterised by a low birth rate and an increasing death rate, which leads to the progressive reduction of the population fit for work.

In 2010 Romania's demographic situation was in regress, continuing the descendant trend begun in 1991. If on July 1<sup>st</sup> 1990, Romania's total population numbered 23.2 million inhabitants, according to the National Institute of Statistics (NIS, 2011), on July 1<sup>st</sup> 2010 it dropped to 21.4 million inhabitants, without taking into account the temporary outbound migration.

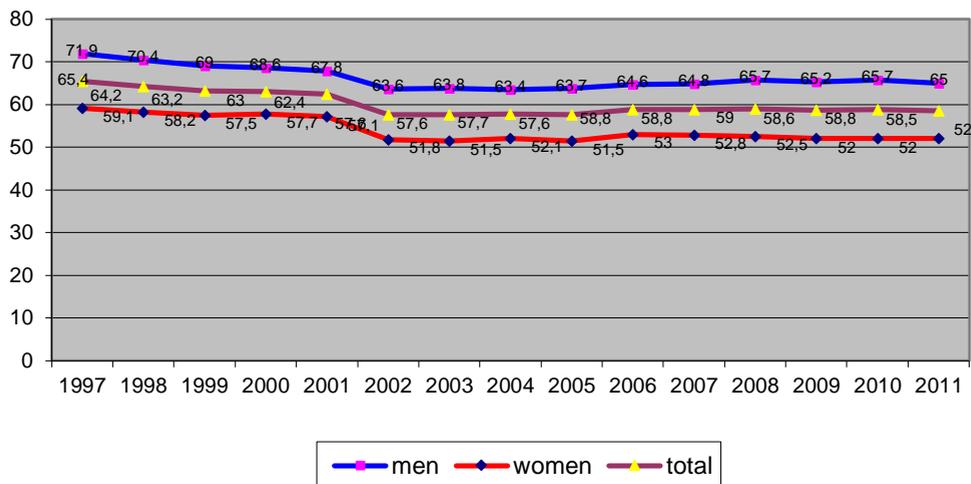

In 2011, *the employment rate* for the population aged between 15 and 64 in the EU was 64.3%, exhibiting a slight growth compared to 2010 (64.1%), nevertheless it remained *below the 70% target set by the Lisbon European Council for 2010.*

In 2011, rates higher than 70% were recorded in The Netherlands (74.9%), Sweden (74.1%), Denmark (73.1%), Germany (72.5%) Austria (72.1%), whereas rates even lower than 60% were registered in Poland (59.7%), Slovakia (59.5%), Ireland (58.9%), Bulgaria (58.5%), Spain (57.7%), Malta (57.6%), Italy (56.9%), Hungary (55.8%), Greece (55.6%) and *Romania* (58.5%). (Eurostat, 2012: 233).

As regards the employment rate among women, the Lisbon European Council set the goal that it reach 60% until 2010 (Eurostat, 2010: 282-283), but this target was not reached, not even in 2001. Thus, in 2011 the employment rate among women was 58.5% in the European Union, considerable lower than the employment rate among men (70.1%). However, in 2011, the employment rate among women was higher than 60% in almost half of the EU member states, and than 70% in Denmark (70.4%) and Sweden (71.8%).

In 2011, whereas the total employment rate in Romania was 58.5%, in the case of women it was only 52%, while the employment rate among men was 65%.

Regarded in time, in Romania the employment rate has exhibited a sinuous evolution, but with a *general descendant trend*, and it had the smallest values in the period 2002-2005 (figure 3). Thus, if in 1997 the employment rate in Romania was 65.4% (71.9% for men and 59.1% for women), in 2011 it was only 58.5% (65% for men and 52% for women).

**Figure 3:** Employment rate in Romania (1997-2011)  
 Source: Elaborated by the authors based on the Eurostat data (2012: 234)

According to Eurostat (2012: 236), the employment rate among people with higher education is, naturally, higher than among people with secondary education and even more so for elementary and middle school graduates.

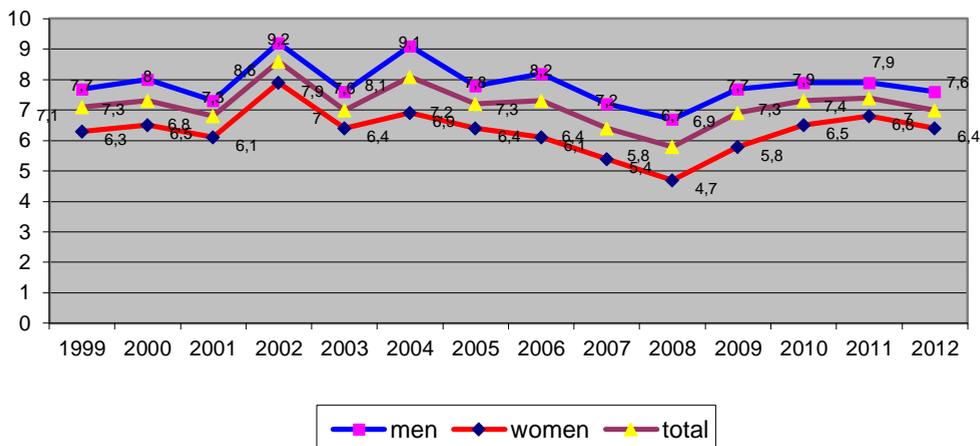

In Romania, in 2011, the employment rate among people with higher education was 82.1% (82.4% in 2010), among people with secondary education 62.3% (62.2% in 2010), and among elementary and middle school graduates 40.5% (43% in 2010). On the other hand, in the European Union, *the unemployment rate* was 9% in 2009, as the economic crisis worsened the unemployment issue, and it reached a 9.7% rate in 2010 and 2011, and 10.5% in 2012.

The highest unemployment rate was recorded in Spain, 21.7% in 2011, and 25% in 2012, and this is one of many reasons why this country is ranked among the last EU countries when it comes to labour market efficiency.

The lowest unemployment rates were registered in Austria (4.2% in 2011, and slightly higher in 2012, more precisely 4.3%), in Luxembourg (4.8% in 2011, and 5.1% in 2012), The Netherlands (4.4% in 2011 and 5.3% in 2012), Germany (5.9% in 2011 and 5.5% in 2012).

Except several countries where the unemployment rate dropped in 2012 compared to 2011 – Germany, Denmark, Estonia, Lithuania, Malta, Finland, UK, Romania – the other countries exhibit a growth of the unemployment rate in 2012.

In *Romania*, the unemployment rate was 7% in 2012, slightly descendant compared to the previous years (7.4% in 2011, and 7.3% in 2010), but higher than in 2008 (5.8%), the year with the lowest values in the last decade (figure 4). In this period (1999-2012), higher unemployment rates were recorded among the male population in 2002 and 2004 (it was above 9%, the highest values in the analysed period).

**Figure 4:** Unemployment rate in Romania (1999-2012)

Source: Elaborated by the authors based on the Eurostat data (2010: 247; 2012: 245)

### 3. Conclusion

Reality has proved that on the macroeconomic level no country has ever recorded a sustained period of economic development without granting a special attention to the human factor.

The stock of human capital existing at a certain moment is an important factor of economic and social growth and development, which is proved by the development of macroeconomic researches focused on education integration into the production functions used in the study of economic growth.

It was found that the countries with highly educated and trained population are the most productive countries from the economic viewpoint.

Thus, as our country exhibits numerous limitations on the labour market, efforts should be made for harmonising individual interests with general, society's interests, as regards training; consequently we must establish the best correlation possible between the youth qualification and economy's requirements.

Education and professional training are the most important investments in human capital, as employees' productiveness depends not only on their capacity for effort and their motivation, but also on the investments made in them, both at the place of work and beyond.

Obviously, the development of human capital is made not only through school education and professional training at the place of work, but also through investment in people's health condition.

Furthermore, we should also focus on career planning, recruitment and hiring of labour force and on the technical and human endowment of these activities with specialised personnel, as well as on labour duration, including workload.

In order to enhance professional planning and training, as well as labour conditions, we must expand the forms of employment (including part-time), in view of securing both for young graduates – "inactivity is a bigger problem among out-of-school youth than unemployment" (Scarpetta and Sonnet 2012: 4-30) – and for older persons a

rapid insertion to the labour market, as well as support from the labour market institutions.

For a labour market to function properly, the employer-employee relation is crucial and in this respect what is important is not only the atmosphere at the place of work, salary calculation and incentives granting or providing professional training courses, but also the way of planning and managing annual vacations, medical leaves or unpaid leaves.

Moreover, as regards human capital issues we must pay attention to those related to regional and national disparities in accumulating human capital, as well as to the problems of over-qualified labour force migration.

Labour market should offer population *the job change flexibility*, including shifting from one type of economic activity to another, fast and at low costs, allowing at the same time salary fluctuations. An efficient labour market should also ensure *a clear relation between the incentives offered to employees and their efforts*, as well as the best use of the available talents - which *includes the equality between men and women in the business environment*.

## SOME CRITICAL ASPECTS CONCERNING THE INSTITUTIONAL SYSTEM OF EUROPEAN UNION

**Abstract:** *In this paper we want to clarify and understand the decisional process in European which is related to the determination of the identity of the Union, answering to several questions concerning the implementation of the European Union into an organization, the different relations with other organizations and with the international law. In the family of the international organizations, the European Union has its own place because it realizes an economic integration project and a political one, a supranational but refusing the traditional categories of constitution and the international law. Qualifying as an international organization sui generis, EU developed a new legal order, deciding to create a supranational organization, formed by Member States and their citizens. The integration process is a permanent challenge opened to a new and developing process for solving all the internal and external problems of the EU. The States have an international "sensitivity" when the application of EU rules exceeds their obligations laid down in the Treaties to third countries and international organizations to which they have not exempted obligations. It was argued that the concept of "demos" or acting people is intrinsically linked to that of the nation-State. The issue of democratic deficit of the European Union is bound to four basic problems: the construction as a whole and therefore of the institutional system, under the principle of conferral, the Union shall act only within the limits that Member States have been conferred in the Treaties to attain the objectives that they set, The Treaty of Lisbon reinforces the legitimacy of the operation of the Union based on free and democratic will expressed by Member States. European construction is achieved through a democratic transfer of competences of the democratic States to a Commission subject to a weak democratic control, while the European Central Bank preserves absolute dominion over its monetary policy outside democratic control. The democratic deficit of the European Union must be judged in the light of the democratic ideal, which led to an ideal-type of political regime, being found itself in constant restructuring, with respect to the evolution of socio-political realities.*

**Keywords:** *decisional process, institutional, European Union, European External Action Service*

**JEL classification:** *K3, K33*

**1. Generally Introduction.** The understanding of the decision-making process in the EU is very closely related to the determination of EU identity by answering a series of questions on enframing in an international organization, its relations with other organizations and international law. Ana M. Lickova shows that in the family of international organizations, the European Union (EU) has a special place because it

realizes a supranational, economic and political integration, but rejecting the traditional categories of constitution and international law ( Lickova, vol. 19, n.3)

EU members have invested its institutions with many internal and external powers, giving rise to complicated international situation. In the EU, its Member States are and remain sovereign entities which mean that its areas of competence were the result of a transfer of competences from the national to the supranational level. The States have an international "sensitivity" when the application of EU rules exceeds their obligations laid down in the Treaties to third countries and international organizations to which they have not exempted obligations. (Ivan, A.L., (2007)

Union's situation is closest to that of the federal states, whose constitutions reserve large areas of autonomy to the sub-federal entities whose international action can cause consequences and affect the whole federation. The absence of international legal personality exempts the sub-federal entities from direct international reactions. In contrast, international sovereignty of EU member states can then expose them to the international obligations arising from wrong acts of supranational institutions.

EU members had to deal with a number of challenges long before the appearance of European Court of Human Rights and the judicial bodies of the International Trade Organizations. In these institutions, the European states have difficulties similar to the difficulties encountered by the traditional federal governments. Governments meet the challenges coming from the international effects of the international legal capacity, where documents are missing or are paradoxically incomplete. (A.M. Lickova ,(1999)

## **2. Analysis and determination of notions.**

### **The Insufficient democratic legitimacy of the EU institutional system.**

As M.V. Antonescu noted, the originality of the EU political system makes the problem of democratic legitimacy to present different aspects independently of each dimension of the Union. On the government side, the legitimacy has in view: the representation of Member States in the EU institutions, the share of votes of each state in the decision-making process, responsibilities of the EU institutions and their relationship to each other. (M.V. Antonescu, (2006)

It may be invoked the "living report" of the European citizens with the institutions, because they need to know the functioning of institutions and participate in their lives. According to the method of initial integration, goals stated by the European Communities were of economic nature. At the same time, some issues related to the implementation of its objectives, in particular those related to the integration of markets, proved to be eminently political. For example, there is the annual agricultural price fixing or the directive on the right of establishment and recognition of diplomas. Other areas that preoccupied the governments of the Member States, rather than on their citizens, as far as affecting the essential interests of the Member States, and in particular, their budgetary balance by transferring funds from the Community and tax harmonization. In some countries, especially in England and Germany, the increased level of transfers to the Community was run by politicians. In addition to the mentioned cases, the Treaty of Maastricht has raised some concerns; particularly those who opposed to the treaty presented it in an apocalyptic picture. Politicians have presented this treaty as trying to create a Super - European State, without its institutional system to work, sometimes being successful only due to general ignorance of the population (M.V. Antonescu, 2006)

Critical issues to the Treaty of Maastricht went from an anachronistic conception of the role of the State and included a series full of contradictions. It was stressed that the areas important to exercise political power were torn out from the democratic constraints. This finding may give the impression that the removal of the political power of the State - nation was by definition an anti-democratic action, thereby prompting a fundamental antinomy between democracy and supranational power. In a similar manner, we mention that popular sovereignty was unique and indivisible, so that the National Assembly was its sole representative. This position implies in particular that the transfer of powers could not be made of a mere strengthening of the powers of the European Parliament.

It was argued that the concept of "demos" or acting people is intrinsically linked to that of the nation-State. Any idea of transnational democracy is beyond any question. Similarly, limited consent of the European peoples is evoked on the European integration process. Finally, it was argued that the democratic deficit is more important to the Community institutions, than it would be at the level of national institutions. In a paper devoted to the crisis of democracy, it is shown that although the democratic ideal is materialized in forms that express the participation of the people in power, democracy is dysfunctionally marked by the de-legitimizing authority, by the fragmentation and disintegration of social groups, the discharge of the core values of democracy: equality and individualism.(M. Crozier, 1977)

### **The Democratic deficit of the European Union.**

Lady Williams, former Minister of the Labour Party in UK defined the democratic deficit as "the distance between the transferred powers to the Community level and control mechanisms from the elected parliaments that is implemented". On the other hand, we must emphasize that "between a union of states and a union of nations, there is a gray area where decisions are likely to spiral out of control" where the confusion between the operation of powers, insufficient legitimacy of institutions, lack of transparency, insufficient democratic control and restricted impact of national parliaments are manifestations of the democratic deficit. This problem does not arise only in the European Union, it equally arises in the nation-state.( Constantin Stephanou, 1997)

The draft Constitutional Treaty had in mind an ambitious European project to propel a more clearly stated political unity, supported including by a symbolism able to express its ability to solve their own problems through a European mechanism more clearly defined, and to manifest itself as an actor with a clear and distinct voice in the international arena. The Treaty not being adopted, the Intergovernmental Conference had the task of developing what was called the reforming Treaty in the sense that it wanted to meet the expectations of the Union's peoples linked to a clearer definition of the identity of the Union, but especially to a democratization of its organization and functioning "closer to citizens", addressing their life problems. It thus seeks an answer to the question raised by the Laeken European Council in December 2001 on equipping the Union with a mechanism to make it more powerful and at the same time closer to its citizens, ie, more democratic. (Clapie, Michel, (2003)

As outlined by Professor *Liviu - Peter Zăpârțan*, the issue of democratic deficit of the European Union is bound to four basic problems.

The first relates to the construction as a whole and therefore of the institutional system, legitimacy expressed by the popular will to confer to some institutions the ability to organize and lead a community based on laws and rules that are respected. In this sense, there can be a lack of legitimacy of the European construction because it is based on Treaties that are ratified by each state according to democratic procedures.

The Treaty of Lisbon considers in this respect that, under the principle of conferral, the Union shall act only within the limits that Member States have been conferred in the Treaties to attain the objectives that they set, so that any competence not conferred upon the Union remain with the Member States. Added to this is the provision of art. 3 § 3 according to which, under the principle of subsidiarity, in areas which do not fall within its exclusive competence, the Union shall act only in so far as the objectives of the proposed action can not be satisfactorily achieved by the Member States, both at central and at regional and local level, but can be better achieved due to the scale or effects of the proposed action at Union level.

The Treaty of Lisbon reinforces the legitimacy of the operation of the Union based on free and democratic will expressed by Member States because the Union institutions apply the principle of subsidiarity according to the protocol of the Treaties and national parliaments ensure the compliance with the principle of subsidiarity in accordance with the procedure laid down in the protocol.

It is believed that in this way the Union's legitimacy is judged through what is it by itself, through its identity and its unique and original way by which it was built, when states and European nations have decided on behalf of common fundamental values and aspirations of peace, security and well-being to assign part of their sovereignty attributes to build a distinct institutional system to balance the interests and wills of the Member States. It is significant in this regard, the statement at art. 8 A according to which the Union operation that is based on representative democracy, meaning that "citizens are directly represented at Union level in the European Parliament: States are represented in the European Council by the Heads of State or Government and in the Council by their governments, themselves democratically responsible either to their national Parliaments, or to their citizens. Art. 9 has changed its content in the Treaty of Lisbon stating that the Union shall have an institutional framework to promote its values, accomplishment of objectives, serving its interests and citizens of the Member States and ensure the consistency, effectiveness and continuity of its policies and actions.

The Treaty, thus, provides a legal basis for the need to have a coherent institutional framework, able to accomplish the goals for which the Union was created as her successes are proofs of that people's needs in a more efficient manner. There is a "unit tax", that is a number of benefits that accrue to people's lives that would not have been able to get in the old formats of the States. Mindful to how the Union institutions relate to their citizens, the Treaty inserts art. 16 A which states that "to promote good governance and ensure the participation of the civil society, institutions, bodies and Union bodies are working in compliance with the highest possible degree the principle of openness, the political nature of the debates in the European Parliament and in the Council ( when it deliberates and votes on a draft legislative act).

*O. Baisné* and *R. Pasquier* stated that the legitimacy of European integration strengthens as it proves its ability to meet the needs of European citizens and more, to anticipate a number of requirements it may have. It is a real change in the national

political space in which European concerns make their way of generating political behaviors, beliefs and values that re-define the political posturing. It would exist, in the interpretation of the two authors, an institutionalization of community roles and rules within each Member State, a statement of the European issues by the national political class. (O Baisné et R. Pasquier, 2007)

Some authors, including *William Outhwaite*, think that after the introduction of the European citizenship occurs a mutation in the particular civil societies that could generate future a civil European society supported by Economic and Monetary Union, by euro, by policies designed to create a freedom, security and justice space. (William Outhwaite, 2000)

A second issue raised by the discussions on the democratic deficit are connected to the representativity of the European institutions and their personnel action. In this respect, it is considered that the democratic deficit would be expressed by a combination of factors:

1. The weakness of the European Parliament (despite increasing his powers after the signing of the Maastricht Treaty). The Council is the true European legislator. In particular, the European Parliament has no control over monetary and trade policy. Elections for the European Parliament record an increasing absenteeism rate: from 37% in 1979, the absence rate reaches 50.6% in 1999 and 55.4% in 2004, hence a lack of democratic legitimacy of the European Parliament.

2. Commission President is not elected, he is appointed by the heads of states and governments under a negotiation between the leaders of the European countries. Commission accumulates functions, so it has a monopoly on initiative right, it sets the application texts of decisions taken by the Council, it performs official duties in the field of competition and it also has the power to sanction.

3. Council members have democratic legitimacy, but the Council legislates on a Commission proposal that does not have its own democratic legitimacy.

4. Decisions made by a qualified majority on trade reveal exclusively from Commission, with secret and opaque intervention of the specialist committee and the lobby – exercised by the interested stakeholders.

Organization of powers is confusing because there are three executive bodies (Competition Commission, European Council and Council of Ministers), two legislative bodies (Council of Ministers and European Parliament) and the concentration of legislative and executive with the Council.

Contrary to the principle of separation of powers inherent in any democracy, the European Union is based on the distribution among the different institutions of features that contribute to the decision making process:

- Proposal belongs to the Commission; the Parliament has only a mere advisory role;

- the Council has decision-making power;

- the Court of Justice sets legal standards;

- the Court of Auditors checks finances;

- Central Bank sets monetary policy.

European construction is achieved through a democratic transfer of competences of the democratic States to a Commission subject to a weak democratic control, while the European Central Bank preserves absolute dominion over its monetary policy outside democratic control. The absence of debate, the Commission's power supported by the Committee 133, the independent role of the Central Bank, the Commission's submission to multinational agencies, the tendency to standardize the

economy, hegemonic tendency of large countries (France, Germany, UK) with respect to the small ones, the complicated language of the Treaties "neo-colonialism" of EU with respect to the South in WTO negotiations, they all complement a picture of Europe's democratic deficit.

The reformation of European institutions is not a simple adjusting to meet enlargement as it was tried by the Treaty of Nice. The reformation of the European institutions involves a fundamental break with Europe in the Treaty of Maastricht, Amsterdam and Nice. In this regard, it may be noted that the Treaty of Lisbon doesn't introduce spectacular provisions on institutional mechanism, but a series of tendencies are noteworthy.

The concept of European democracy is enshrined in Title II which provides provisions relating to the principles of democracy on which the European construction is designed: according to art. 8 the democratic equality is enshrined stipulating that "in all its activities, the Union shall respect the principle of equality of its citizens, who benefit from equal attention from its institutions, bodies and agencies; art. 8 enshrines the idea that the functioning of the Union shall be founded on representative democracy so that every citizen has the right to participate in the democratic life of the Union, and its decisions are made as openly and closer to the citizens, while respecting the principle of subsidiarity; the dual legitimacy of Union is enshrined, by the will of states to respect the precepts of democracy, but also by the will of the people, which leads to the assertion of the need to establish cooperation between national parliaments and the European Parliament to improve the mechanism of co-decision.

The Treaty of Lisbon defines especially three levels of democratic compliance will of the people of the Union, national, states and peoples and European level will have to be based on the will of citizens.

Article 8B explicitly requires as the European institutions to maintain a constant, open and transparent dialogue with the civil society, with all the stakeholders interested in solving European problems.

Citizen initiative is stimulated by the provision of section 4 of article. 8B which states that at least one million citizens who are nationals of a significant number of Member States may invite the Commission to draw up a proposal for a legal act deemed necessary.

It should be noted that according to art. 8C, the role of national parliament's increases in the construction of the Union, in its good operation, throughout the European public life, working together, ensures the principle of subsidiarity, assessing the European policies.

All these together includes the "democratic deficit" of the EU operation because it induces the "constitutionalization" of the ultra-liberal economic model, recorded mainly in the 332 articles of the third part of TEC (comprising a total of 448 items) ignoring other possible scenarios of the European construction.

**3. In conclusion:** The Community political system tends to come closer to the American or Swiss model, rather than the German model. These three systems coincide with the Community system in relation to the issue of central bank independence. In the latter case, the absence of a central government and parliamentary control allow the ECB to act only after their own logic imposed by the treaties, without knowing a counter - power. Even the implementation of a European government responsible in front of the European Parliament and of the European Council eventually, it would be on the transformation way of the current Union into a

federal entity, an inevitable stage as long as they would realize that the democratic deficit stems from the absence of such institutions.

The democratic deficit of the European Union must be judged in the light of the democratic ideal, which led to an ideal-type of political regime (in the Weberian sense of the term), being found itself in constant restructuring, with respect to the evolution of socio-political realities. A proof of this is the fact that altogether with the strengthening of the unity of the European peoples appeared new requirements of organization and management at the institutional level, to which the sequence of treaties tried to answer them. The Treaty of Lisbon is subscribed to this philosophy that will represent the basis of a future reforming treaty when the degree of European integration will increase.

*Abstract: Porquier (1984) defines the exolingual communication as the communication between individuals who do not share a common language, in opposition to endolingual communication, which is the communication between individuals sharing the same native language. Calling in this opposition, our paper brings forward the problem of intercomprehension and incomprehension in the endolingual space. Intercomprehension is nowadays almost exclusively associated to plurilinguism and a series of curricula of foreign language simultaneous learning. It is considered that the exolingual situation is by excellence a state of communicational risk and its management is more difficult, for it does not guarantee the success in communication. Polarizing the research in this direction unfortunately casts a shadow on the opportunity of debates on intercomprehension in one's native tongue. And this is due, as Tyvaert (2008) showed, to the fact that "we should avoid pretending from linguistic intercomprehension what cannot be accomplished by intralinguistic intercomprehension". It is naturally acceptable that the lack of intercomprehension leads to incomprehension, therefore to the misinterpretation or annulment of communication between people speaking the same language. In the context of linguistic training of future economists, we consider that the lack of intercomprehension in one's native tongue often originates in the deficiencies of speciality knowledge. Therefore, we can state that an economist who does not understand an economic message in his native tongue cannot generate "endolingual intercomprehension". According to a recent study on a representative sample of students from the Faculty of Economic Sciences of Oradea, we have tried to prove the above hypothesis and to render the students sensitive regarding the study of foreign languages. The results entitle us to consider that the lack of intralinguistic intercomprehension (due to deficiencies in the speciality field) leads to incomprehension, diminishes the person's willingness to start a plurilingual communication, thus compromising the chance of an interlinguistic intercomprehension, so necessary to the contemporary geostrategic space.*

## Préambule

Rémy Porquier (1984 : 17) définit la *communication exolingue* comme la communication établie entre les individus qui ne partagent pas une langue maternelle commune, par opposition à la *communication endolingue*, qui est établie entre des individus qui ont une langue maternelle commune.

L'intérêt pour l'intercompréhension (dorénavant IC) se manifeste aujourd'hui prioritairement dans le champ exolingue, en relation avec la didactique des langues étrangères. Nous présenterons en ce qui suit quelques lignes générales qui définissent *l'intercompréhension exolingue* et nous nous arrêterons ensuite à *l'intercompréhension endolingue*, avec une extension vers l'apprentissage des langues étrangères sur objectifs spécifiques.

### 1. L'intercompréhension et la communication exolingue

L'une des définitions les plus usuelles de l'intercompréhension appartient à Doyé (2005 : 7), qui la décrit comme « l'activité de personnes de langues maternelles différentes qui communiquent en s'exprimant dans leur propre langue et en comprenant la langue de l'autre ». L'intercompréhension est aujourd'hui un concept incontournable dans le champ exolingue. Elle est prioritairement associée au plurilinguisme et à une série de programmes d'apprentissage simultané des langues étrangères, dont nous retenons : EuRom4, dirigé par Claire Blanche-Benveniste à Aix-en-Provence, Galatea, initié par Louise Dabène à Grenoble, EuroComRom, développé à Frankfort par Horst G. Klein ou InterCompréhension Européenne (ICE), programme conduit à Reims par Eric Castagne et J.-E. Tyvaert.

L'intercompréhension se sert, en tant que dispositif de formation, d'une structure formelle et pragmatique propre, avec des acteurs qui ont une représentation exacte des entraves de la communication. La situation exolingue est, en contexte communicatif, une situation de risque, maîtrisée grâce à l'habileté des participants qui gouvernent non seulement la situation linguistique et les effets de parenté linguistique, mais aussi des configurations culturelles et interculturelles. Les apprenants doivent prendre en compte le fait que les langues étrangères *a priori* inconnues, ne le sont cependant pas. Nous pouvons considérer, dans cette perspective, qu'« il apparaît indispensable, pour des raisons d'efficacité, de tenir compte de l'acquis antérieur de l'apprenant » (Dabène, 1994 : 37).

Dans notre pratique d'enseignement-apprentissage, nous nous revendiquons du programme InterCompréhension Européenne (ICE), où l'on considère que l'expérience devient un « outil de communication plus efficace que les mots » (Castagne, 2004). Une catégorie importante de savoirs est représentée par les connaissances non linguistiques : chaque apprenant dispose d'un ensemble de connaissances que l'on appelle encyclopédiques et qui entrent dans son capital personnel. L'un des défis des enseignants de langues étrangères serait d'amener les apprenants « à prendre conscience de différentes catégories de connaissances dans lesquelles ils pourront trouver des clés d'interprétation » (Doyé, 2005 : 14) et d'exploiter efficacement toutes les ressources dont ils disposent : les connaissances générales, culturelles, situationnelles, comportementales, pragmatiques, scripturales, à côté des connaissances purement langagières (phonologiques, grammaticales et lexicales). Tous ces composants sont activés lors de l'intercompréhension à des degrés qui varient selon les personnes et les contextes.

On pourrait donc anticiper que la communication exolingue est fortement dépendante des connaissances que les apprenants dominent dans leur langue maternelle, c'est-à-dire dans des circonstances de communication endolingue.

## 2. L'intercompréhension et la communication endolingue

La discussion sur l'intercompréhension dans la communication endolingue peut paraître un truisme, au regard d'une question telle que « pourquoi a-t-on besoin de parler d'intercompréhension puisque la compréhension est de mise entre des interlocuteurs qui parlent une langue commune ? ». La problématique de l'intercompréhension entre les membres d'une même communauté n'est cependant pas sous-entendue et elle représente le fondement sur lequel peut se dresser la communication exolingue.

Malgré les préjugés, le terme d'*intercompréhension* apparaît dans plusieurs domaines, dont celui économique (en relation avec le développement organisationnel, la délibération publique, les pratiques de négociation, la culture entrepreneuriale, etc.). Si les spécialistes mettent en discussion le besoin d'intercompréhension, c'est parce que vraisemblablement elle n'apparaît pas toujours entre les parleurs d'une même langue.

L'observation des ressources lexicographiques auxquelles nous avons eu accès témoignent d'une transition terminologique : l'appréhension de l'IC comme phénomène complexe multi-facettes (Degache et Melo, 2008), acquérant une spécialisation certaine dans la didactique (Ferrão Tavares *et al.*, 2010 ; Jamet, 2010) trouve ses sources dans la perception de l'IC comme phénomène objectif propre à une communauté qui partage la même langue ; dans ce sens, nous retenons une première approche de l'IC endolingue comprise comme « une notion technique utilisée par les linguistes et les anthropologues qui déterminent sur le terrain [...] les limites entre parlers, dialectes et langues » (Blanche-Benveniste, 2008 : 41). Cette acception est commune à la sociolinguistique et elle représente le point de départ pour toutes les portées actuelles de l'intercompréhension.

**Une autre approche, qui figure dans les éditions du *Petit Larousse* depuis 1998, retient la définition synthétique d'un terme spécialisé, circonscrit au domaine linguistique « *intercompréhension = ling. compréhension réciproque* » (cf. Jamet, 2010, la première mention du terme dans ce dictionnaire daterait de 1988). **Dans le sens de cette définition, l'*intercompréhension* est un phénomène qui sous-tend une série de processus de communication entre des personnes qui parlent la même langue et travaillent dans des milieux qui supposent une compréhension réciproque sans faille, afin d'éviter les *incompréhensions*.****

Dans la communication endolingue avec des interlocuteurs unilingues, ceux-ci partagent idéalement les mêmes savoirs linguistiques, ce qui ferait croire que l'*intercompréhension* des communicateurs est une évidence. Or, malgré le partage de la langue commune, plusieurs situations d'*incompréhension* relèvent de la situation endolingue : « l'*incompréhension* règne dans les relations entre les humains [...] Elle est quotidienne, omniprésente, planétaire, elle enfante les malentendus » (Morin, 2004 : 121).

Dans le cadre endolingue, on retiendra le cas des langages des professions, générateurs d'*incompréhension* intralinguistique : « Les variétés linguistiques ne sont pas simplement dues au fait qu'on a du portugais, de l'italien, du danois [...] mais aussi parce que certains parlent mathématiques, d'autres parlent droit, d'autres

parlent anatomie, d'autres parlent politique, et que les difficultés qu'on a à se retrouver dans ces langues posent de nombreux problèmes » (Authier, 2004 : 56).

Si dans le cas de la communication endolingue l'incompétence linguistique peut représenter un facteur de séparation, dans la communication exolingue elle peut devenir un élément catalyseur, qui met en place des stratégies autres que celles purement linguistiques. Nous reprenons à Authier l'exemple des bûcherons de toute l'Europe réunis en France pour discuter de leur profession : l'excellence dans le domaine n'était pas doublée d'une excellence linguistique, parce que non seulement ils avaient une maîtrise des langues européennes extrêmement lacunaire, mais la plupart parlaient le patois d'origine. En dépit des conditions communicatives impropres, ils avaient atteint une compréhension satisfaisante favorisée par « un être ensemble bien particulier », né de la pratique et des intérêts communs, qui transcendaient les insuffisances linguistiques (Authier, 2004 : 55).

Ci-dessus, nous avons montré que l'intercompréhension renvoie prioritairement à l'enseignement-apprentissage de plusieurs langues de la même famille, dans des programmes qui se distinguent de la formation traditionnelle. Mais l'intercompréhension est bien un composant central dans tout apprentissage de langues étrangères, tel qu'il se présente habituellement dans les établissements scolaires européens. Nous aborderons en ce qui suit le rôle de l'intercompréhension endolingue dans le monde professionnel, en relation avec l'apprentissage d'une langue étrangère sur des objectifs spécifiques.

### **3. Sensibilisation des étudiants économistes à l'apprentissage des langues étrangères**

Certes, on apprécie que l'absence de la compréhension, c'est-à-dire l'*incompréhension* dans la langue maternelle, empêche l'*intercompréhension* des locuteurs qui parlent la même langue ; par voie de conséquence, elle influe d'abord sur l'apprentissage d'une autre langue étrangère et ensuite sur l'intercompréhension des locuteurs qui utiliseraient plusieurs langues. Les propos de Tyvaert (2008 : 254) sont suggestifs : puisque « rien ne nous assure de nous intercomprendre parfaitement entre locuteurs d'une seule et même langue, on se gardera d'exiger de l'intercompréhension interlinguistique ce qui n'est pas réalisé par l'intercompréhension intralinguistique ».

L'hypothèse de départ est que les étudiants apprennent une langue étrangère s'ils mettent en œuvre consciemment toutes les ressources dont ils disposent. L'expérience nous a démontré que l'une des résistances des apprenants à l'apprentissage des langues étrangères, plus particulièrement du français langue étrangère, tient à la perception d'une *déficience au niveau linguistique* : les étudiants ont presque toujours la conviction d'une incompétence personnelle, manifestée en relation avec la grammaire, le vocabulaire et la phonétique de la nouvelle langue, en l'occurrence du français. Or, la démonstration suivante prouvera que la principale source des hésitations interlinguistiques réside dans ce que nous pourrions nommer l'*incompétence encyclopédique*, qui sous-tend une incompétence professionnelle plus ou moins problématique.

Afin de sensibiliser les étudiants économistes à l'apprentissage du français des affaires, qu'ils considèrent en général comme une langue difficile, nous avons réalisé une petite étude exploratoire sur un échantillon de 63 étudiants de la Faculté des Sciences Économiques d'Oradea.

### 3.1. Étude

L'étude a été réalisée dans le cadre d'un cours de français langue étrangère, IIe année d'études (spécialisations finances et banques, comptabilité et informatique de gestion, management, affaires internationales, économie du commerce, du tourisme et des services). Les fragments choisis pour la présente analyse ont été extraits d'un matériel non-didactisé, représentant l'étape de l'exploitation didactique des documents authentiques de profil économique, en français et/ou en roumain.

Un simple essai de traduction de fragments de textes du roumain en français, sans difficultés grammaticales ou lexicales particulières, a relevé des syncopes au niveau de la maîtrise des termes en langue maternelle. Par l'observation du comportement des apprenants, nous avons retenu la perception générale de ceux-ci : la source de la difficulté de traduire les phrases en français résiderait, selon eux, dans la difficulté même de la langue française. Vu la récurrence de cette situation didactique, nous avons décidé de réaliser un exercice qui les détermine à reconsidérer leur point de vue.

Tout d'abord nous avons retenu 3 phrases, extraites de trois articles au sujet économique d'actualité, publiés sur des sites spécialisés consacrés. Nous avons demandé aux étudiants d'expliquer (par écrit), dans leur langue maternelle, le sens global des phrases exposées ; afin d'éloigner le stress dû à une situation d'examen scolaire, une note ludique a été attribuée à cette démarche, par l'introduction d'un personnage imaginaire, un jeune adulte qui n'est pas spécialiste du domaine économique et qui demande des explications simples, dans la langue maternelle, à propos de la signification des fragments examinés. Ce personnage imaginaire a eu le rôle de reconstituer une situation de communication réelle et possible, fondée sur l'intercompréhension intralinguistique.

Ensuite, nous avons examiné les réponses des étudiants, concluant sur certains points qui ont confirmé l'exigence d'une compétence professionnelle dans la langue maternelle.

Deux précautions s'imposent : premièrement, on admet l'effet de contagion qui détermine les étudiants à s'inspirer l'un de l'autre, malgré les consignes explicites de l'enseignant ; deuxièmement, on reconnaît l'influence de la spécialisation des étudiants sur l'appréhension de l'un ou de l'autre des termes. Les étudiants, si réactifs cependant dans une situation de vérification classique des connaissances, n'ont pas réclamé la présence de quelque thème non-étudié. Ils ont tous reconnu la pertinence de la maîtrise des concepts visés, indépendamment du domaine de spécialisation (d'autant plus qu'il s'agissait de termes habituellement véhiculés dans les journaux télévisés).

### 3.2. Discussion

Le besoin de la démonstration nous a déterminée à introduire un argument de contraste : deux phrases sans aucun lien avec l'économie (l'une extraite d'un article de physique et l'autre retirée d'un article d'informatique) ont été ajoutées à la série de 3 phrases aux sujets économiques. Les phrases soumises ont été les suivantes : *Phrase 1* : Informația cuantică este foarte fragilă și nu poate fi clonată, astfel că pentru a preveni alterarea ei sau chiar pierderea de informații, este necesar controlul total asupra tuturor componentelor rețelei. Cea mai mică memorie staționară pentru informația cuantică este atomul, iar fotonii reprezintă mijlocul perfect de transmitere a sa ([www.stiintasitehnica.com](http://www.stiintasitehnica.com)).

*Phrase 2* : Câteva din noile funcționalități introduse în SQL Server 2008 sunt configurarea bazată pe politici a suprafeței expuse, management extensibil a cheilor de criptare, Criptare/Decriptare transparentă a datelor ([www.revistait.ro](http://www.revistait.ro)).

*Phrase 3* : Ratingurile de suport și ratingurile pentru datoriile pe termen lung și scurt ale UniCredit Țiriac Bank, Zagrebacka Banka și ZAO UniCredit Bank se bazează pe potențialul sprijin disponibil de la banca mamă UniCredit S.p.A. Confirmarea ratingurilor lor de suport la '2' reflectă opinia Fitch că UniCredit S.p.A. va continua să sprijine aceste subsidiare ([www.capital.ro](http://www.capital.ro)).

*Phrase 4* : FMI oferă „oportunitatea“ guvernului să reducă arieratele și să eficientizeze companiile de stat ([www.zfr.ro](http://www.zfr.ro)).

*Phrase 5* : Nu sunt incluse în sfera de aplicare a prezentei ordonanțe de urgență creanțele înscrise la masa credală în cadrul unei proceduri de insolvență ([www.just.ro](http://www.just.ro)).

Après un premier aperçu de l'ensemble, nous avons commencé le test proprement dit et nous avons enregistré les observations suivantes : à la lecture de la première phrase, tous les étudiants ont refusé une explication, ont ri et ont décliné clairement leur compétence ; à la lecture de la deuxième phrase, 2 étudiants sur les 63 examinés ont essayé timidement de donner une explication, justifiant leur compétence (l'un d'entre eux étudiait aussi l'informatique et l'autre était un passionné du domaine).

La lecture des trois phrases suivantes a relevé, à quelques exceptions près, d'un même paradigme. Nous n'avons pas voulu faire un examen polarisé de chaque phrase, ayant seulement l'intention d'identifier certaines lignes qui caractérisent le rapport des apprenants à ce type de situation authentique et soulignant un cadrage qui pourrait être pris en compte dans le processus d'enseignement-apprentissage. Chaque situation a été ensuite mise en relation avec un niveau plus complexe d'intercompréhension, à savoir l'intercompréhension exolingue dans une communication d'affaires ; le schéma est illustré avec des exemples tirés des réponses (en roumain) données à la troisième phrase, aménagés de certaines conduites des apprenants.

### 3.3. Proposition d'analyse

**Incompréhension intralinguistique totale** (celle qui pourrait influencer radicalement sur une décision d'affaires)

- *reconnue par écrit ou à l'oral, avec honnêteté (déclinaison assumée de la compétence):* « Je ne sais pas. », « Je n'en ai aucune idée. » ;
- *reprise exacte et intégrale du texte source ;*
- *simple reformulation du texte* utilisant un changement de topique : « UniCredit Țiriac Bank, Zagrebacka Banka și ZAO UniCredit Bank se bazează pe potențialul sprijin disponibil de la banca mamă UniCredit S.p.A. pentru ratingurile de suport și ratingurile pentru datoriile pe termen lung și scurt. » ;
- *information extrêmement sommaire* : « băncile sunt sprijinite de Unicredit S.p.A » ;
- *compréhension erronée* : « Fitch este director. » ou « Fitch este un grup important în cadrul băncii. »

- **Compréhension intralinguistique approximative** (prémisse d'intercompréhension parcellaire, celle qui pourrait influencer partiellement sur une décision d'affaires)
- *compréhension correcte, mais incomplète* dans l'économie de la signification du texte en langue maternelle : « cele trei bănci sunt sprijinite de banca mamă; ratingul se referă la anumite cote ce trebuie atinse de o bancă, cote ce se referă în principal la aspectele financiare. ». Dans un nombre important d'explications de ce type, on remarque l'absence de référence au terme « Fitch » ;
- *compréhension partiellement correcte, partiellement incorrecte* : ce modèle reprend le type de situation exposée *supra*, avec la mention que les termes « Fitch » ou « rating » ne sont pas correctement expliqués ;
- *actualisation d'un sens secondaire* d'un terme économique repéré dans le texte ; par exemple, dans le cas du mot « rating », 3 étudiants ont évoqué le sens propre aux analyses média : « ratingul reprezintă o anumită instituție, un canal TV. ».
- **Compréhension intralinguistique totale** (garantie d'intercompréhension et de décision d'affaires correcte)
- *saisie du sens précis de la phrase* ; formulé sous une forme ou une autre, ce type d'interprétation surprend le sens correct de la phrase, à savoir la disponibilité ou la capacité de la banque mère d'assurer le besoin de capital et les liquidités pour les banques filles énumérées. On retient également l'élargissement des explications vers d'autres termes, les analogies, l'enrichissement du contenu (par exemple, « Toate băncile amintite sunt filiale ale băncii mamă, UniCredit S.p.A. Ratingurile se referă la nivelul la care este percepută banca. Dacă ratingul este mic, atunci băncile vor pierde clienți. Dacă pierd clienți, înseamnă că nu vor mai realiza venituri. Fitch este o organizație care dă note băncilor și le încadrează în diferite niveluri. »).

### 3.4. Interprétation quantitative

L'interprétation quantitative fournit les résultats suivants : incompréhension totale – 12 cas sur les 63 examinés, à savoir 19%; compréhension approximative – 41 cas sur 63 examinés, à savoir 65%; compréhension correcte et totale – 10 cas sur les 63 examinés, à savoir 16%. Les limitations d'espace ne permettent pas d'exposer ici toutes les analyses concernant les autres phrases au sujet économique. Nous retenons cependant qu'elles s'inscrivent, sans différences notables, dans le même paradigme, les pourcentages correspondants se situant aux alentours des mêmes scores : environ 20% incompréhension totale, plus de la moitié compréhension approximative et environ 15% compréhension correcte.

## 4. Conclusions

La prise en compte des manifestations d'incompréhension et d'intercompréhension endolingues qui interviennent dans la formation des étudiants en sciences économiques, à savoir les futurs professionnels de l'économie, nous conduit à l'identification des relations suivantes :

- le manque de compréhension en langue maternelle (endolingue) est synonyme d'*incompréhension* en langue maternelle (endolingue) ;

- l'*incompréhension* en langue maternelle (endolingue) ne génère pas d'*intercompréhension* en langue maternelle (endolingue) ;
- l'absence d'*intercompréhension* intralinguistique (endolingue) empêche l'*intercompréhension* exolingue.

Certaines conduites sont parlantes pour la relation que les apprenants instituent avec la tâche didactique, en rapport avec une situation d'incompréhension ou d'intercompréhension : quand l'incompréhension est partagée par tous les membres d'un groupe, elle est « mieux vécue » (elle est reconnue à haute voix, en unanimité, étant accompagnée de rires et de regards complices). Alors que dans un groupe il y a plus de deux ou trois personnes qui comprennent le contenu, deux types de réaction sont saisissables : soit on leur demande de mutualiser les connaissances, soit on cache difficilement les sentiments de culpabilité (regards de travers, hésitations ou grimaces).

Nous pouvons conclure sur trois aspects d'ordre général : tout d'abord, dans un contexte endolingue professionnel, l'*incompréhension* d'un message (à l'écrit ou à l'oral) rend impossible son traitement ultérieur dans une langue étrangère ; ensuite, l'*intercompréhension* unilingue erronée ne peut se fonder que sur un traitement erroné et elle a toutes les chances de générer une *intercompréhension* exolingue fautive ; finalement, l'*intercompréhension* unilingue partielle conduit à une *intercompréhension* exolingue partielle, tandis que l'*intercompréhension* totale s'avère être une source d'*intercompréhension* exolingue pertinente.

Il est donc impérativement nécessaire que la mise en place des compétences langagières en langues étrangères s'associe aux connaissances circonscrites au domaine professionnel et dominées dans la langue maternelle. On ne peut pas enseigner aux étudiants économistes le français des affaires (et à la rigueur l'anglais ou l'allemand des affaires) si les étudiants ne maîtrisent pas le vocabulaire des affaires dans leur langue maternelle.

# RECEPTION OF SPOKEN ENGLISH. MISHEARINGS IN THE LANGUAGE OF BUSINESS AND LAW

**Horea Ioana - Claudia**

University of Oradea, Oradea, Romania

[ihorea@uoradea.ro](mailto:ihorea@uoradea.ro)

**Abstract:** *Spoken English may sometimes cause us to face a peculiar problem in respect of the reception and the decoding of auditive signals, which might lead to mishearings. Risen from erroneous perception, from a lack in understanding the communication and an involuntary mental replacement of a certain element or structure by a more familiar one, these mistakes are most frequently encountered in the case of listening to songs, where the melodic line can facilitate the development of confusion by its somewhat altered intonation, which produces the so called mondegreens. Still, instances can be met in all domains of verbal communication, as proven in several examples noticed during classes of English as a foreign language (EFL) taught to non-philological subjects. Production and perceptions of language depend on a series of elements that influence the encoding and the decoding of the message. These filters belong to both psychological and semantic categories which can either interfere with the accuracy of emission and reception. Poor understanding of a notion or concept combined with a more familiar relation with a similarly sounding one will result in unconsciously picking the structure which is better known. This means 'hearing' something else than it had been said, something closer to the receiver's preoccupations and baggage of knowledge than the original structure or word. Some mishearings become particularly relevant as they concern teaching English for Specific Purposes (ESP). Such are those encountered during classes of Business English or in English for Law. Though not very likely to occur too often, given an intuitively felt inaccuracy - as the terms are known by the users to need to be more specialised -, such examples are still not ignorable. Thus, we consider they deserve a higher degree of attention, as they might become quite relevant in the global context of an increasing work force migration and a spread of multinational companies.*

**Key words:** verbal communication; mondegreens; teaching EFL; mishearings in ESP classes.

**JEL classification:** Y80; Z00; K00.

## 1. Preliminary remarks

Oral communication presents certain peculiarities given the fact that the filters interposed between the speaker and the hearer are more numerous than in written English.

### 1.1. Faulty perception of spoken language

Spoken language can provide grounds for occurrence of faulty reception. "Mondegreens are a sort of aural malapropism. Instead of saying the wrong word, you hear the wrong word ... Mondegreens are in a sense the opposite of malapropisms; they result from something being misheard rather than missaid ...

The word mondegreen is generally used for misheard song lyrics, although technically it can apply to any speech.” (Austin, 2008)

Research into the matter of perception of spoken English sometimes provides examples of mishearings but does not necessarily name the phenomena as “mondegreens” and does not discuss or analyse the concept, which would not be the point anyway. The matter is rather the diagnosis of the misperceptions and the attempt to better understand the process of misperception in order to be able to preempt it. As demonstrated by Linda Shockey, non-natives are very likely to interpret and decode the sequence of sounds they hear, in a way more familiar to them: “We assume that a lack of familiarity with casual speech is a major factor in their lack of comprehension.” (Shockey, 2003: pp.120-1)

Psychological and environmental factors intermingle in the perception process. This results in a peculiar distortion of the sounds heard or in a particular construction of meaning attributed to some uncertain collection of sounds. An inadequate or poor knowledge and comprehension of the notions heard combined with a personal propensity or a predisposition to react towards fulfilling various expectations on the background of a particular cultural and intellectual baggage on part of the receiver are faced with a sometimes tricky or misleading syntactical structure. This is often new or unfamiliar and maybe delivered at a high speech rate, with a certain accent or a sophisticated intonation, or perhaps lacking an appropriate quality not only if the sound is recorded.

### **1.2. Definition of the term ‘mondegreen’**

So, what is a mondegreen and how did it come into being? “A mondegreen is a word that is construed as it is actually heard, not as the speaker intends it to be heard ...” (Safire, 1994) “Although some linguists have called this stumblepunning ‘unwitting paronomasia,’ the better word is mondegreen. Coiner is the writer Sylvia Wright, who noted in a 1954 Harper’s article that some children happily sang in church of ‘Gladly, the cross-eyed bear,’ when the hymn was ‘Gladly the cross I’d bear.’ She remembered the Scottish ballad ‘The Bonny Earl of Murray’ and how she had recited it as a child: ‘They have slain the Earl Amurray, / And Lady Mondegreen.’” (Safire, 1994) Of course, “It eventually transpired that Lady Mondegreen existed only in the mind of Sylvia Wright, for the actual lyrics said that they ‘slay the Earl of Murray and laid him on the green.’” (Safire, 1994) “And to this day Lady Mondegreen’s name has been used to describe all mishearings of this type!” (Austin, 2008)

## **2. The usual mondegreen**

Researchers in the field of linguistics have become more and more aware of the phenomenon and it quickly acquired the status of phonetic process. As William Safire notices, “In a 1987 essay in Time magazine, Gregory Jaynes found a way of surviving the stress of New York City: He recalled a pastor’s asking him in his youth to rise and sing Hymn No. 508, ‘Lead On, O Kinky Turtle.’ Later, he found it had been intended as ‘Lead On, O King Eternal,’ but ‘in the days since, the phrase lead on, o kinky turtle has assumed a profound significance in the course of my wanderings. I use it in a kind of incantatory fashion, muttering ‘lead on, o kinky turtle’ whenever I feel shorted, stiffed, put upon by outside forces.’” (Safire, 1994)

## 2.1. Famous examples

The most famous mondegreens (Feldman, 2007), given as examples in almost all contexts where the theme is discussed, seem to be:

- In lyrics:
  - "Excuse me while I kiss this guy", instead of "Excuse me while I kiss the sky" - Jimi Hendrix in Purple Haze,
  - "The girl with colitis goes by", misheard for "The girl with kaleidoscope eyes" - The Beatles in Lucy in the Sky With Diamonds
  - "There's a bathroom on the right", for "There's a bad moon on the rise" - Creedence Clearwater's Bad Moon Rising
- In the medical field: "Varicose veins" heard as "Very close veins"
- In mass-media: "Paper View TV" understood instead of "Pay-per-view TV."

## 2.2. Common mondegreens

Some other examples of common mondegreens, as remarked by researchers (Cowan and Rakusan, 1998; Edwards, 1995; Kissell, 2008; Nordquist, 2013) or at the Center for the Humane Study of Mondegreens (Carroll, 2003: E-12), can be seen in table 1, a collection showing that researchers into the field particularly relied and focused on lyrics. This comes only natural as it is in songs that mondegreens are more often. (see also Austin, 2008) People are used to communicate plainly, to speak and hear at the normal pace, rate, rhythm, tonality and intonation of the standard discourse. The peculiar melody or the sometimes forced pace of the lyrics may trigger a new combination of syllables or a more familiar structure, for instance.

**Table 1:** Examples of common mondegreens

<i><b>Mondegreen</b></i>	<i><b>Original</b></i>	<i><b>Origin</b></i>
"Are you going to starve an old friend?"	"Are you going to Scarborough Fair?"	Scarborough Fair, Simon and Garfunkel
"Baking carrot biscuits."	"Taking care of business."	Takin' Care Of Business, Bachman-Turner Overdrive
"Bohemian Rap City"	"Bohemian Rhapsody"	Queen
"Born under a bad sign with a boom boom in your eyes."	"Born under a bad sign with a blue moon in your eyes."	A3, Woke Up This Morning
"Bring me an iron lung."	"Bring me a higher love."	Higher Love, Steve Winwood
"Crimean River."	"Cry Me a River."	Cry Me a River, Julie London
"Dead ants are my friends; they're blowin' in the wind."	"The answer my friend is blowin' in the wind."	Blowin' In The Wind, Bob Dylan
"Donuts make my brown eyes blue."	"Don't it make my brown eyes blue."	Don't It Make My Brown Eyes Blue, Crystal Gale
"Got a lot of lucky peanuts."	"Got a lot of love between us."	Let's Hang On. Frankie Vallee and the Four Seasons

<i>Mondegreen</i>	<i>Original</i>	<i>Origin</i>
"Hope the city voted for you."	"Hopelessly devoted to you."	Hopelessly Devoted to You, Grease
"I blow bubbles when you are not here."	"My world crumbles when you are not here."	I Try, Macy Gray
"I got no towel, I hung it up again."	"I get knocked down, but I get up again."	Tubthumping, Chumbawumba
"I never had me a better time in a textile mill, oh my,"	"I never had me a better time and I guess I never will"	Crocodile Rock, Elton John
"I'll be your xylophone waiting for you."	"I'll be beside the phone waiting for you."	Build Me Up Buttercup, The Foundations
"I'll never leave your pizza burning"	„I'll never be your beast of burden"	Beast of Burden, The Rolling Stones
"I'm a pool hall ace."	"My poor heart aches."	Every Step You Take, The Police
"Just brush my teeth before you leave me, baby."	"Just touch my cheek before you leave me, baby."	Angel of the Morning, Juice Newton
"Mama don't take my clothes 'n' throw 'em away."	"Mama don't take my Kodachrome away."	Kodachrome, Paul Simon
"Midnight after you're wasted."	"Midnight at the oasis."	Midnight at the Oasis, Maria Muldaur
"... no ducks or hazards in the classroom."	"... no dark sarcasm in the classroom"	Another Brick in the Wall, Pink Floyd
"She's got a chicken to ride."	"She's got a ticket to ride."	Ticket to Ride, The Beatles
"Sweet dreams are made of cheese"	"Sweet dreams are made of these"	Sweet dreams are made of these, Eurhythemics
"Sleep in heavenly peas."	"Sleep in heavenly peace."	Silent Night, Christmas carol
"The ants are my friends"	"The answer, my friend, is..."	Blowing in the Wind, Bob Dylan
"What a nice surprise when you're out of ice."	"What a nice surprise bring your alibis."	Hotel California, Eagles
"You and me and Leslie."	"You and me endlessly..."	Groovin', The Rascals
"You make the best homemade stew around."	"You make the best of what's still around."	When The World Is Running Down, The Police

### 3. Mishearings in ESP classes

Next, some similar situations, met as a lecturer at the University of Oradea, teaching English at the Faculty of Economics and the Faculty of Law, will be presented. Funny surprises discovered in papers written on various listening materials, called forth a

deeper research into the matter and more careful examination of the notes students took. Further observations and some experiments both in dictation and listening comprehension revealed the presence – if not really regular, than at least often enough to be pertinently considered a relevant phenomenon – of mistakenly perceived phrases.

### 3.1. “Pearls” in Business English classes

Several examples of such ‘pearls’, as we are accustomed to name the “logic-linguistic confusions”, can be seen in table 2.

**Table 2:** Selection of mishearings met during Business English classes

<b>Original fragment</b>	<b>Misheard structure</b>
Under these terms, they hived off the retail operation	And he disturbs the height of the retail operation
Payment’s now past due	Payments go part stewed
Bargaining comprises of all these	Burden income prizes and all fees
Bidding means putting forward a proposal	Building is good in form of the proposal
Avoid default under the promissory note	If all the fault and all the promise are remote
The bill came to five grands	Then Bill Gates won high rates
Out of pocket expenses were paid back	Out of packages pence for a paid bag
He paid in cash and checked his change	He paid in cash on chequed exchange
There is high level maintenance on the free market	This hardly ever meant announcing a flee market
The bottles were hand wrapped	The bottles were hard trapped
Passengers who booked cabins	Passing chairs to look at this
On board you’ll be entitled to free meals	Abroad he’ll be in the title of two-three mails
They ‘il have the surcharge refunded	They have this new judgment founded
They retained the distinctive long-necked glass	They retained the instinct of a non-backed class

**Source:** author’s design on own data

We can note that while some misinterpretations are totally outside the field of business, rather illogical and quite hilarious, most examples preserve or try to retain a certain mark of the domain, yet. Still comical, as they attempt to fit in the context but hardly manage to, we can assume that the minds of the subjects must have struggled to somehow keep the register, to stay in some way inside the fields of business.

As English is a language much used in the filed of business, tourism, international trades, transportation, international affairs, marketing and other domains of communication – speaking, hearing and understanding – in this ‘lingua franca’ of the world economy, and, given the fact that mistakes can easily occur with non-natives - yet not only with non-natives-, this aspect of the process of mishearing might prove quite relevant.

A business meeting, a presentation, a telephone conversation or a negotiation might lead to odd results if participants ‘hear’ something different from what was said or

unintentionally ‘interpret’ the sounds heard, construing a new phrase, like in the old game of ‘the wireless phone’. Not very common – as the very nature of the specific terminology used does neither logically nor normally allow even margins, let alone large ranges, of potential interpretation –, but, nevertheless, possible, such mishearings demand a certain attention and could benefit from a deeper investigation.

### 3.2. Occurrence in classes of English for Law

Fixed expressions and strict terminology of proceedings are very unlikely to create confusion in the minds of those who have been trained and work in the field of law since they are familiar with the lexical particularities and the specific notions and concepts of their profession. All the same, the non native students preparing for the field of law in a non-English language might have problems with the terminology of English juridical language which they approach during the university years. They only deal with it during their first two study years and are not too probable to use it in an English speaking court environment, for instance. That is because the law system differs and specialised studies would be required for someone to be allowed to work in the English law system. Still, some mishearings might appear in their activity when researching and tackling documentation, when going to conferences or talking to a non-native English speaker about professional matters.

Some examples of misperceptions of law terminology encountered during classes of English with law students can be seen in table 3. Unlike with students in economics, as seen in table 2, we shall note that the register is now in most cases changed to a standard one. There are now rather scarcely preserved instances of juridical discourse as this is, indeed, more difficult to construe.

**Table 3:** Mishearings met during English for Law classes

<i><b>Original text</b></i>	<i><b>Misheard structure</b></i>
Improper appropriation of funds in one’s keeping	In a proper preparation he finds the housekeeping
Misdemeanour is not punishable by imprisonment	Mister Minnor is now punishing one of the prisoner
Plea bargaining is resorted to so as to speed up trial	Plea bargaining is resulted if she asked to speak of trial
They sent a subpoena to summon the witnesses to court	They sent us some peanut and to some of the witnesses a card
The libel refers to written defamation	The liable returns a written information
Confess against the promise the sentence will be lighter	Confess that great supporters of sentence will delight her
The court extended the protection	The court is bent in the profession
Measures that grant suspects the benefit of due process of law	Assures the grand suspects the bona fide to process the law
The Chancellor of the Exchequer controls the public finances	The chance of those that win a cheque can close the public finances

**Source:** author’s design on own data

Even if rarely likely to occur, mistakes in the perception of terminology of law might have rather unpleasant outcomes. We can imagine, for instance, the consequences

that can be brought about, in bureaucracy and formalities, by an official document of the court that is issued containing such mistakes as a misplaced punctuation, a defective linkage of syllables or even missing words, due to a mishearing and a wrong transcription of the procedures.

#### 4. Conclusions

A particular failure in perceiving speech, often seen as a funny perception mistake, mondegreens are mostly encountered when it comes to lyrics as it is in songs and poems that sounds might be distorted by a certain imposed rhythm. Yet, misperceived terms may arise in other fields, too. From dry, silly or really dull, to mildly amusing, odd, or plainly ludicrous, the erroneous hearing of certain words or phrases may spring from any listener faced with whatever speaker – more or less experienced, native or not. It is doubtless that all domains of life and activity may register instances of the aforementioned mishearings, and with learners of English it comes all just natural.

Having a rather limited occurrence, these special ‘mondegreens’ or mishearings in professional activities – if these ‘mistakes in hearing’ can be applied as such to the said domains – are not, in our opinion, of a very extensive occurrence. Thus they cannot be considered to produce relevant negative effects. Still, the presence of these sorts of misperceptions noticed during the English classes with non-philological students, i.e. students not trained philologically, should at least stir attention and drag awareness to the fact that unintended puns can emerge, or, rather, be received and interpreted wrongly, even in the most formal fields of human activity.

## ECONOMY, ECONOMICS, ECONOMIC, ECONOMICAL

**Sim Monica Ariana, Pop Anamaria Mirabela**

*Department of International Business, Faculty of Economic Sciences, University of Oradea, Oradea, Romania*

[msim@uoradea.ro](mailto:msim@uoradea.ro)

[mipop@uoradea.ro](mailto:mipop@uoradea.ro)

**Abstract:** *To speak and understand a language means - among many other things - knowing the words of that language. The average speaker knows, hears, understands and uses thousands of words daily. But does he use them appropriately? For this reason the paper is why this paper is about words and meanings. More specifically, it deals with the internal structure of complex words, i.e. derivatives. Therefore, the purpose of the paper is to enable students and potentially other individuals dealing with English language on business basis to engage in their own analyses of some aspects of the language, namely the family tree of the word economy. After having read the paper, the reader should become familiar with the necessary knowledge regarding differences between meanings, misuse and actual sense of words deriving from economy, be able to systematically analyze data and relate his own findings on theoretical language problems. English is used by hundreds of millions speakers and still there is always need for improving our knowledge continuously. Knowing and speaking approximate English may not be enough at an advanced level as in the case of students who prepare themselves for careers that involve proficient communication in a foreign language on specific business issues. This is where the idea of such a paper appeared: students of the Faculty of Economic Sciences talk about economy and all the other terms deriving from it, with approximate knowledge of their meaning, without even being aware that some 'minor' suffixes like -ic, -ical, -ics etc. really matter and do make a difference. Consequently, we started our teaching of Business English lecture in September 2012 with a working sheet based on the terms economic/ economical/ economics/ economy to assess students' awareness of these terms. The result was not a surprise as more than 90% misused economical instead of economic. That seemed a perfect introduction for students in economics. From that moment on, the building of their specific vocabulary could start.*

**Keywords:** *economy; economics; economic; economical; -ic/-ical adjectives*

**JEL classification:** Y90

### **Introduction. Dictionary considerations.**

For a better understanding of all the nuances the words in questions may have, we will proceed with several dictionary considerations.

*Economy* 1. careful management of resources to avoid unnecessary expenditure or waste; thrift; 2. a means or instance of this; saving; 3. sparing, restrained, or efficient use, esp. to achieve the maximum effect for the minimum effort e.g. economy of language; 4. a. complex of human activities concerned with the

production, distribution, and consumption of goods and services; b. particular type or branch of such production, distribution, and consumption, e.g. a socialist economy, an agricultural economy; 5. the management of the resources, finances, income, and expenditure of a community, business enterprise, etc. 6. a. a class of travel in aircraft, providing less luxurious accommodation than first class at a lower fare; b. (*as modifier*) e.g. economy class; 7. *modifier* offering or purporting to offer a larger quantity for a lower price e.g. economy pack; 8. the orderly interplay between the parts of a system or structure e.g. the economy of nature; 9. (*philosophy*) the principle that, of two competing theories, the one with less ontological presupposition is to be preferred; 10. (*archaic*) the management of household affairs; domestic economy.

*Economics* 1. *functioning as singular* the social science concerned with the production and consumption of goods and services and the analysis of the commercial activities of a society; 2. *functioning as plural* financial aspects e.g. the economics of the project are very doubtful.

*Economic* –adjective 1. of or relating to an economy, economics, or finance e.g. economic development, economic theories; 2. (*British*) capable of being produced, operated, etc. for profit; profitable e.g. the firm is barely economic; 3. concerning or affecting material resources or welfare e.g. economic pests; 4. concerned with or relating to the necessities of life; utilitarian; 5. *a variant of* economical; 6. (*informal*) inexpensive; cheap.

*Economical* –adjective 1. using the minimum required; not wasteful of time, effort, resources, etc. e.g. an economical car, an economical style; 2. frugal; thrifty e.g. she was economical by nature; 3. *a variant of* economic (sense 1), economic (sense 2), economic (sense 3), economic (sense 4); 4. (*euphemistic*) deliberately withholding information (esp. in the phrase economical with the truth). (<http://www.collinsdictionary.com/english-thesaurus>)

There is another useful observation at this point, regarding the word *economy* and its derivatives: there is a divergence of the pronunciation of the word family based on *economy* /ɪˈkɒnəmi/ - *economics* /,i:kəˈnɒmɪks/, *economise* /ɪˈkɒnəˌmaɪz/, *economic* /,i:kəˈnɒmɪk/, *economical* \,i:kəˈnɒmɪkəl \ and this is mainly due to the 'length' of the first vowel.

## 2. Introduction to word formation and affixation in English. Adjectival suffixes

The adjectival suffixes of English can be subdivided into two major groups (Ingo Plag, 2002:118). A large percentage of the derived adjectives are *relational adjectives*, whose role is simply to relate the noun to the adjective that qualifies the base word of the derived adjective. For example, *economic thinking* means 'a thinking having to do with economy, referring to economy, characterized by economy', *institutional regulations* means 'regulations having to do with institution requirements', etc.

On the other hand, there is a large group of derived adjectives that express more specific concepts, and which are often called *qualitative adjectives*. Sometimes relational adjectives can adopt qualitative meanings, as can be seen with the derivative *technical*, which has a relational meaning 'having to do with technique' in the sentence *He is a technical genius*, but which also has a qualitative sense 'conforming to the rules of technique', as in *This is a technical problem*. Thus, relational adjectives occur only in attributive position, creating what Plag (2002) calls as *prenominal* modifiers (as in *a technical problem*) and when found in predicative

position in a clause (as in *This sentence is technical*), they usually have adopted a qualitative sense.

## 2. 1. Word formation. *-ic* and *-ical* adjectives

A very interesting and productive phenomenon of English word-formation is that of *-ic* and *-ical* adjectives such as *economic/economical*. This whole group of adjectives formed with *-ic* and *-ical* suffixes poses several problems to linguists and language teachers likewise with consequences in their use, thus affecting students as well. To support the idea of being one of the trickiest elements of English in use, here is, for instance, the question: *Is it 'electric cord' or 'electrical cord'?* Although hardly scientific or academic, a simple Google search reveals 184,000 results for 'electric cord' and 274,000 for 'electrical cord' While the latter option is the clear winner, a very sizable minority uses the former. To make matters even more confusing, in some instances the distinction appears relatively clear. English speakers would probably feel that 'electric guitar' is a much better choice than 'electrical guitar'. Similarly, English speakers would probably vastly prefer 'electrical engineering' to 'electric engineering.' (Silas McCracken, 2009)

According to Stefan Th. Gries (2001b) there are two main issues regarding this group of suffixes: first of all, the difficulty to detect any pattern governing the distribution of suffixes: when does an adjective end in *-ic* only and when does it end in *-ical* only? And further, for the cases when one adjective root takes both suffixes (*historic(al)* etc.), what problems do we encounter: are the two forms a pair synonymous, or to what degree do the two newly formed adjectives differ in meaning or is their different meaning expressed only by means of these affixations or is there some other possibility to distinguish between the different adjective forms?

It seems that the morphological rules in English regarding *-ic* and *-ical* are quite complex, perhaps suggesting that the meanings of forms with *-ic* and *-ical* have either become more similar or have diverged over time. Consider numeric/numerical, *botanic/botanical* which appear almost interchangeable. Conversely, there are pairs with different meanings: *classic* refers to 'belonging to the highest class or degree' whereas *classical* refers to the culture of ancient Greece or Rome or it may also refer to works of art of the so called *classical* period in the 18th century (*I am studying classical languages.*); *comic* refers to artistic comedy comic opera and *comical* means 'funny' (*She had a comical expression on her face.*); *politic* means wise, prudent or shrewd while *political* means 'connected with politics'.

Being a relational suffix, *-ic* attaches to foreign bases (nouns and bound roots). Quite a number of *-ic* derivatives have variant forms in *-ical* (*electric - electrical, economic - economical, historic - historical, magic - magical* etc.). Sometimes these forms are clearly distinguished in meaning in other cases it remains to be determined what governs the choice of one form over the other.

Roughly speaking, there are two categories of attitudes regarding the choice of one suffix over the other: on the one hand, there are very pessimistic researchers (Ross, 1998:41–43, Fowler, 1926:249) claiming that the choice is often immaterial; Snell (1972:57) considers that: *'If and when similarly formed adjectives end in -ic or -ical cannot be determined by rules'*; on the other hand, there are other theoreticians who formulated some more or less scientific rules or observed certain pattern in making the choice: *'the forms in ic may indicate either the quality or the category of thing, but that those in -ical always, or almost always, indicate the quality only [...] I dare*

say this is no more than a tendency, but I think it exists' (Jespersen, 1942:391), or Marchand (1969) tried to conclude that *-ic* adjectives derive from the 'basic substantive', whereas *-ical* adjectives in turn derive from *-ic* adjectives. The idea was echoed by Hawkes (1976:95) who argues that: *'the adjective in -ic, derived from the root substantive, has a semantically more direct connexion with that root idea; the adjective in -ical, a derivative of itself from an adjective form, has a looser connexion with the root idea and often takes on a correspondingly looser meaning'*. The same proposal is embraced by dictionaries, i.e. according to Collins English Dictionary and Thesaurus *-ical* is 'a variant of *-ic*, but [has] a less literal application than corresponding adjectives ending in *-ic*', but no example is discussed. When making the distinction between the two suffixes, another idea emerged: adjectives ending in *-ic* denote more specific/scientific meanings, whereas adjectives ending in *-ical* refer to more general/ common meanings. In Table 1 there is a visual, schematic representation of some possible distinctions between *-ic* and *-ical* adjectives:

**Table 1:**

<i>-ic</i>	<i>-ical</i>
quality and category	quality
direct connection to root substantive	less direct connection to root substantive
specific	less specific/ more general
genuine	resembling/ imitation
positive	less positive/ negative
Scientific terms	wider/ common use

Source: Findings and claims on *-ic/-ical* adjectives, Stefan Th. Gries, A corpus-linguistic analysis of English *-ic* vs *-ical* adjectives, 2001:75

Nevertheless, the findings and proposals of pattern presented do not all hold up to scrutiny. Obviously, there are some adjectives that are distinguished by the help of their ending: *politic(al)* and *economic(al)*). However, most of them do not seem to follow any rule. Neither recent dictionaries nor recent studies could clarify on the matter. Thus, *'if one intends to examine the contemporary usage of particular adjectives, the use of corpus data is a much more reliable way to pursue'* (Gries, 2001:79). In his attempt, Gries proposes an analysis of the pairs of adjectives following the patterns of proposed generalizations presented in Table 1. and concludes that they often apply only to a limited set of adjectives (while not applying to other adjectives where the distinction would also make sense); they are in some cases contradicted by the data (Gries, 2001:80).

Thus, referring to the *-ic/-ical* pair of adjectives we can summaries:

- English has a number of parallel adjectives with *-ic* and *-ical* endings;
- These endings are similar in their forms and origins but somewhat different

in their meanings and uses.

- There is no rule or consistent pattern governing the formation of adjectives ending in *-ic* and *-ical*. Some *-ic* words are preferred over their *-ical* counterparts (e.g. *ironic* over *ironical*), and vice versa *-ic* counterparts (e.g. *metaphorical* over *metaphoric*, *alphabetical* over *alphabetic*).
- When in doubt about which form is preferred or whether an *-ic/-ical* word pair has differentiated, the only way to know for sure is to check a dictionary or other reference source – for that you really have to become aware of that possibility and not ignore it.

## **2.2. Economic and economical: economic pertains to economy; economical means not wasteful.**

### **2.2.1. Difficulties in using economic and economical**

The synonymous pair *economic/economical* may pose difficulties. ‘Economic’ and ‘economical’ are two adjectives that are frequently used interchangeably. They are clearly related but they have distinct meanings. According to the *Oxford English Dictionary*, the definition of *economic* is ‘relating to economics or the economy’; however, *economical*, means ‘giving good value or return in relation to the resources used or money spent; sparing in the use of resources or money’.

When talking about ‘the economic situation’ or ‘the economic outlook’ of a country, i.e. where we are discussing ‘the economy’, then the adjectival suffix *-ic* is preferred:

e.g. The host will interview the winners and losers from current *economic* situation.

There was a rise in unemployment due to the *economic* downturn.

The *economic* outlook in this country is now bleaker than at any time in the last ten years.

It’s not about money - he is fine from an *economic* perspective.

However, when referring to making personal economies and saving money, we tend to use *economical* as it also means using the minimum amount of time or energy.

e.g. The most practical and *economical* way to see Canada is by air.

An *economical* car uses a minimum amount of gas to drive a maximum number of miles.

Politicians are invariably *economical* with the truth.

We wanted to make the most *economical* use of our time.

The main confusion arises when using *economic* and the actual meaning is *economical*, like in the phrase ‘economical with the truth’, which is a euphemism for lying, being deceitful, brought into popular usage by the British civil servant Robert Armstrong. Who used the phrase correctly, but many do not as they do not get the actual meaning, thinking of economy-related issues, i.e. ‘economic with the truth’ ([http://en.wikipedia.org/wiki/Economical\\_with\\_the\\_truth](http://en.wikipedia.org/wiki/Economical_with_the_truth)).

The same confusion appears, nevertheless in phrases like ‘economical domain’, ‘economical studies’ when the real meaning has to do with economy or economics and not with being thrifty or saving money, like in following example taken from a blog, thus showing the wide interest dedicated to this topic:

‘A local furniture store used to advertise, ‘We’re feeling the economical pinch...’ with a big banner ad in the newspaper. The store finally went out of business. I couldn’t help thinking it was because they didn’t understand the difference between ‘economic’ and ‘economical’.’

In colloquial English, the distinction between the two words is often blurred, but it is always useful to know the correct meanings, especially when your job is or will be dealing with this field of study.

If we look at the data, we find that:

- *economic* and *economical* are not completely different but share some significant collocates (*processes, reform, repair* etc) which can be interpreted in either way;
- *economic* and *economical* can be synonyms in two senses only:
  1. Things relating to the economy. e.g. You could speak of *economical* growth, although *economic* growth is more common.
  2. Using the minimum amount of effort or resources. e. g. You could speak of someone making *economical* use of their time. *Economic* would also work in that context.

In other words, when meaning wealth, financial rewards, or the science of economics, *economic* should always be employed; on the other hand, *thrifty* or *frugal* can only be replaced by *economical*.

### 2.2.2. Challenges in teaching economic and economical to students

Becoming aware of the troubles and confusions created by *economy* and its family tree we decided to dedicate some time to explaining our students the differences in meanings and their semantic values, pointing out the hilarious effects of their misuse in some context. Consequently, we started our teaching of Business English lecture in September 2012 with a working sheet based on the terms *economic/ economical/ economics/ economy* to assess students' awareness of these terms. The result was not a surprise as more than 90% misused *economical* instead of *economic*. That seemed a perfect introduction for students in economics.

Here is the working sheet used to introduce the topic of economy in our Business English lecture:

#### 1. Mind-mapping and brainstorming

Figure 1.

#### 2. Quiz

Use the discovered words - *economy, economics, economic, economical* - to fill in the empty spaces:

1. I got an \_\_\_\_\_ flight to Spain for £99 return.
2. What has gone wrong with the \_\_\_\_\_ system during the last ten years?
3. The house has a very \_\_\_\_\_ heating system so bills are not a big problem.

4. We have to keep fares high enough to make it \_\_\_\_\_ for the service to continue.
5. You should use your resources \_\_\_\_\_.
6. She thought herself as an \_\_\_\_\_ housewife.
7. Larger tubes of toothpaste are more \_\_\_\_\_.
8. \_\_\_\_\_ is the oldest of the social sciences.
9. A market \_\_\_\_\_ is one in which the price of goods is fixed according to both cost and demand.
10. I got an \_\_\_\_\_ flight to Spain for £99 return.
11. Many people believe that inflation leads to \_\_\_\_\_ decline.
12. This country has an industrial \_\_\_\_\_.
13. He studied \_\_\_\_\_ at Harvard University.
14. It is not always \_\_\_\_\_ for buses to run on Sundays.
15. A small car is more \_\_\_\_\_ than a large one.
16. There has been a slow down in \_\_\_\_\_ activity recently.
17. The government's management of the \_\_\_\_\_ has been severely criticised.
18. Everybody is convinced that the President's new \_\_\_\_\_ policy will bring about an improvement in the American \_\_\_\_\_.
19. Further inflation would endanger our \_\_\_\_\_ seriously.
20. He is studying for a degree in \_\_\_\_\_.

### 2.3. *Economy and economics*

Starting from the assumption that *economics* is a dangerously heterogeneous notion, it is the branch of knowledge concerned with the production, consumption, and transfer of wealth, the study of how society uses its scarce resources and that *economy* refers to a social system that produces, distributes, and consumes goods and services in a society, the wealth and resources of a country or region, we express our intention of performing a brief analysis of the two terms in order to discover which of the two versions: *economy/economics* deals better with what is ordinarily understood as economic. And this is a necessity coming from the experience of translating curricula after curricula, documents describing the objectives, requirements and contents of the domains to be found at The Faculty of Economic Sciences. Do we say either 'World Economics' or 'World Economy' based on what semantic grounds?

Although the general tendency is to consider translation as something that anybody can do with the help of a dictionary, producing a written text using another text as a basis is actually a much more complex phenomenon. And it becomes even more complex when the text in question deals with specialized subjects such as economics. Thus, the ability to interpret specific information requires some knowledge about the syntactic and morphological structure of the foreign text, beside terminological, cultural, contextual, conceptual aspects. Translating these terms bothers (or it should) all kind of categories and here is a genuine example:

*Hello to everybody!*

*Could you please explain what's the difference between these two terms - Economics and Economy. I have to translate some information about my university into English but I've been troubled by the name of the department. What's the most acceptable one - The Department of Management and Economy*

of Nature Use or The Department of Management and Economics of Nature Use? Thank you!

Source: <http://www.usingenglish.com/forum/ask-teacher/141358-economics-economy.html>

As previously affirmed, there is a family of words related to *economics*: *economy*, *economic*, *economically* and naturally there is the corresponding science, *economics*. We refer to *economy*, as the system or set of economic interactions of a whole society; we can also speak about the economy of a person or a firm. The English words *economy* and *economics* can both be traced back to the Greek words οἰκονόμος, namely the one who manages a household, a compound word derived from 'Oikos' means household and 'Nomos' management. Going back in time, for Aristotle, *economics* was a practical, a moral science and 'the economic' referred to the use of what is needed to achieve the Good Life (*Politics*, I). It is linked to material 'human' necessities; this is a 'field-determined' notion of economics as opposed to the 'discipline-determined science' as Crespo distinguishes (2007: 2). Further, the art of household management was applied by the Greeks to the governing of polis (i.e. a city or state) and the term *economics* was applied by them to the governing of state or city. For this reason *economics* was originally called *political economy*. It was Alfred Marshall who first used the term *economics* for *political economy*, in his 1890 book *Principles of Economics*.

According to Adam Smith, political economy was '[a] branch of the science of the statesman' (*Wealth of Nations*, Book IV, Introduction), consequently stressing the same 'field-determined' notion of *economics* referring to practical or moral science. Crespo (2007: 3) considers that the evolvement toward a discipline-determined science began in the 19<sup>th</sup> century.

According to Thomas Carlyle, a 19<sup>th</sup>-century Scottish writer, *economics* is a 'dismal science' that has been described in many ways, few of them flattering. The most concise, non-abusive, definition is the study of how society uses its scarce resources.

Today, the range of fields of study examining the economy gravitates around the social science of economics, but may include other field of study as well: sociology, history, geography. Practical fields directly related to the human activities involving production, distribution, exchange, and consumption of goods and services as a whole, are engineering, management, business administration, applied science, and finance.

Today, the art of household management is practiced by everybody, from governments to common individuals for managing day-to-day economic problems. Thus, in the modern or practical sense, *economics* means management or solution of the day-to-day economics problems, arising from unlimited wants and limited resources, by economizing or wise distribution of the limited resources among different uses; *economics* is the science that studies how human beings try to satisfy their unlimited wants with limited means or resources.

Thus, *economy* is the state of the finances, purchasing, jobs, imports, exports, etc of a country, state, province, region, etc.; *economics* is a subject that studies economies and their various aspects, thus referring to the science.

#### 2.4. Illustration of different usages of *economics* and *economy*

To be sure I often broke this rule, as people are apt to do with rules of the kind; it was not possible for a boy to wade through heavy articles relating to English politics and *economics*, but I do not think I left any paper upon a literary topic unread, and I did read enough politics, especially in Blackwood's, to be of Tory opinions; (*My Literary Passions* by Howells, William Dean, <http://www.thefreedictionary.com/economics>)

While much had been done in England in tracing the course of evolution in nature, history, *economics*, morals and religion, little had been done in tracing the development of thought on these subjects. (*The Analysis of Mind* by Russell, Bertrand, <http://www.thefreedictionary.com/economics>)

At last they gave it up as hopeless, and shook the dust of the shorthand schools, and the polytechnics, and the London School of *Economics* from their feet for ever. (*Pygmalion* by G.B. Shaw <http://www.thefreedictionary.com/economics>)

She told Helen that he always called on Sundays when they were at home; he knew about a great many things--about mathematics, history, Greek, zoology, *economics*, and the Icelandic Sagas. (*The Voyage Out* by Woolf, Virginia, <http://www.thefreedictionary.com/economics>)

Effects of inflation were felt at every level of the *economy*.

John Stuart Mill, By a mighty effort of will, Overcame his natural bonhomie And wrote 'Principles of Political *Economy*' (Edmund Clerihew Bentley, *Biography for Beginners*, 'John Stuart Mill', <http://quotes.yourdictionary.com/economy>)

No *economy* ever stands still. (Sir Roy Harrod, *The British Economy*. <http://quotes.yourdictionary.com/economy>)

Our policy is directed not against any country or doctrine, but against hunger, poverty, desperation and chaos. The purpose shall be the revival of a working *economy* in the world so as to permit the emergence of political and social conditions in which free institutions can exist. (*Speech at Harvard, 5 Jun, announcing the European Recovery Plan (ER A) that became known as the Marshall Plan.* (George C(atlett) Marshall,

<http://quotes.yourdictionary.com/economy>)

Samples of names of university subjects: *Political Economy, Labour Economics, Institutional Economics; Econometrics, Financial Economics, Growth Economics, Data Processing Systems and Applications in Economics etc.*

### 3. Conclusions

The purpose of defining terms is to understand meanings, nature, characteristics and limitations as possible. Knowing as much as possible is our purpose as teachers. Knowledge of *economics* gives you a unique perspective of the world community and is an essential tool for good decision making. *Economic* ideas and principles are used by world leaders and corporate executives to make decisions that change the course of human history. How do government budget deficits and debt affect the *economy*? Many drivers will still be looking to cut their fuel consumption by investing in more *economical* cars.

## L'ÉTUDE DES LANGUES MODERNES ET LA RESPONSABILITÉ POUR LA MIGRATION QUALIFIÉE

**Stanciu Daniela, Ștefan Liana**

*Université de l'Ouest de Timișoara, Faculté d'Économie et d'Administration des Affaires, Timișoara, Roumanie*

[destanciu@yahoo.fr](mailto:destanciu@yahoo.fr)

[stefanliana@yahoo.fr](mailto:stefanliana@yahoo.fr)

**Abstract:** *Among the “vicious” or “secondary” personal mobility effects, the brain drain has become the most disturbing trend for the least developed countries barely out of communism. Its consequences on social and economic development have not yet been measured.*

*We suggest a reflection on solutions (only few at present) that our university finds in order to adapt to the international transfer of human capital. Starting from the responses to questions about the aspirations and migration projects of students from the Faculty of Economics and Business Administration, aspiring entrepreneurs, we have been able to observe a radical change in attitude towards the historical migration.*

*Although the migration phenomenon is considered as being natural in any tumultuous period of history, the current migration differs from the twentieth century one, because it is caused by the growing rate of unemployment and the inability of the people to create new jobs.*

*Young people are sort of exiled because some do not want to leave the country as their precedecessors from the communist regime, but they are pragmatic and want higher salaries. In the case in which they leave the country, they do it having in mind the thought of returning at the moment they find an opportunity in Romania.*

*The Romanian educational system displeases the young by its nature, too theoretical and less practical, by the scarcity of offers of internships in companies. The paradox is that few of the students go study for bachelor and master degrees abroad, although they acknowledge the superiority of the Western education system. The survey shows that while studying abroad, the majority of students get a job, also because the scholarship does not cover their living expenses.*

*Students go abroad for a high quality of life, professional opportunities and for recognition of the individual value. They are attracted by lower corruption, possibilities of professional development and appreciation of their work by the employer.*

*Those of them who decide to come back are justified by numerous opportunities to launch a new business, opportunity to exploit its expertise in order to change the Romanian society. Emotional connection with friends and family and not least patriotism are mentioned by almost all respondents, which is a surprise to a generation considered to be cosmopolitan.*

*Knowledge of foreign languages and intercultural accommodation with the Western civilization through university studies, smooth the progress of migration, but they are not its cause.*

**Key words :** *globalisation, migration qualifiée, fuite des cerveaux, rapatriement*

## **Classification JEL : F22**

### **1. Introduction**

L'ère de la globalisation a eu des conséquences rapides en Roumanie qui a vu sa main d'œuvre, qualifiée ou non qualifiée, quitter en masse une économie fragile. Pour cette économie qui n'a pas encore retrouvé son chemin depuis 1989, les conséquences sont graves et à long terme. Parmi les plus évidentes sont la désertification du marché de la main d'œuvre, la fluctuation du PIB et la fausse croissance économique, la perte des élites, l'incapacité d'assurer un enseignement de qualité et l'anéantissement du système médical.

Comme Alan Winters et Maurice Schiff (2004), nous considérons que les avantages de la fuite des cerveaux sont peu importants par rapport à ses désavantages, surtout dans le domaine de l'enseignement où il faut assurer la continuité des élites et du savoir, de l'intérêt pour la recherche et la conservation de l'identité culturelle. Les conséquences sont encore plus graves pour les pays de petite ou moyenne taille comme la Roumanie.

L'objectif de l'article est de constater la situation présente dans notre université pour ensuite trouver des solutions pour déterminer nos étudiants à rester en Roumanie et contribuer au développement de notre économie.

### **2. Les étapes de la migration de la main-d'œuvre roumaine**

La migration de la main-d'œuvre roumaine hautement qualifiée est un phénomène historique qui se continue avec les mêmes caractéristiques et presque les mêmes chiffres : ceux qui étaient pro occidentaux avant 1989 sont partis après. Nous constatons plusieurs étapes durant les cinquante dernières années à partir des cycles politiques traversés :

#### **2.1. Entre 1948-1989**

La fin de la deuxième guerre mondiale et l'avènement du «communisme », caractérisés par la «dictature du développement» (Roman, 1999) et le manque de libertés sociales et de pensée. Les modalités de départ des intellectuels et des autres catégories de la population étaient :

- la fuite illégale vers les États-Unis et le Canada, mais aussi en Europe Occidentale (après une excursion, une visite de parents, un stage professionnel, etc.) avec un passage obligé dans un campus de réfugiés quand ce n'était pas la prison correctionnelle de retour dans son pays d'origine ;
- la « vente » d'Allemands et de Juifs à destination de leurs pays d'origine ;
- les réfugiés politiques et économiques, les dissidents du parti communiste et les autres mécontents du régime qui demandaient l'asile politique et profitaient d'une aide matérielle sérieuse pour des raisons de propagande anti-communiste. Les bruits courent que pour l'Allemagne, en récompense de la renonciation au droit de propriété (sur la maison ou l'appartement nationalisés) de Roumanie, un vrai pécule était donné comme prime d'installation à l'insu des Allemands natifs, qui se seraient révoltés d'un tel commerce.

## **2.2. Entre 1989-2007**

Le mouvement anti-communiste qui a écroulé le dictateur Ceaușescu, actuellement regretté par une partie de la population, la plus démunie qui soit, et l'adhésion de la Roumanie à l'UE sont considérés de plus en plus comme une acceptation conjoncturelle, payée par de petites trahisons envers nos «frères» Serbes et par une alliance sans réserves à toutes les décisions américaines, à l'encontre de la «vieille» Europe, qui fut pourtant notre alliée traditionnelle depuis la création de l'État roumain moderne.

Ce qui caractérise cette deuxième période, ce sont les nouvelles modalités de départ qui sont apparues :

- une taxe de départ officielle, payée par le migrant après des interviews à l'Ambassade du Canada (de l'ordre de milliers de dollars par personne pour la zone anglaise et un peu moins pour le Québec qui voulait encourager l'identité française) ;
- la loterie des visas pour l'Amérique du Nord, programme qui se déroule à présent encore et qui sélectionne des métiers et des personnes ayant des études supérieures : ingénieurs, médecins, infirmiers, professeurs ;
- La structure des migrants a changé durant cette période car une nouvelle catégorie de migrants apparaît, les sans études supérieures, agriculteurs en Espagne et en Italie et travailleurs dans le bâtiment qui se déplacent tous vers l'Europe occidentale, le Royaume-Uni y compris.

## **2.3. Après 2007 jusqu'à présent**

C'est la période qui a suivi notre adhésion à l'UE. Il y a deux tendances à prendre en compte : la continuation de la migration des ouvriers agricoles pauvres, mais en revanche on assiste au début de la migration intellectuelle massive non seulement vers l'Amérique du Nord, mais surtout vers l'Europe Occidentale. Certains métiers sont privilégiés : médecins et professeurs. À vrai dire, ce sont les deux catégories dépréciées par le pouvoir politique, découragées par des salaires très bas par rapport aux autres catégories professionnelles, situation maintenue même après l'abrogation de la loi de la salarisation unitaire, le 22 novembre 2010 qui a eu comme résultat une diminution des salaires de 25 %, une continuation des licenciements (30 000 en 2011) et la suppression de toutes les allocations et aides, sauf celles visant le travail de nuit.

En même temps nous déplorons le manque de données statistiques fiables relatives aux Roumains qui prennent la décision de rester pour une période de leur vie à l'étranger, s'ils sont forcés par la situation économique précaire ou poussés par l'ambition de se réaliser en quittant un pays qui ne leur offre aucune possibilité de s'épanouir, de développer leur savoir-faire, leur savoir ou leur génie à des fins altruistes et sociétales. Anna Ferro dans son étude les Roumains à l'étranger a la vision la plus correcte et la mieux vérifiée, à notre avis, par rapport à cet aspect de la migration d'une main d'œuvre hautement qualifiée, à savoir chercheurs, masterants ou doctorants : « Ce n'est pas le travail en soi qui m'a poussé à émigrer, mais la combinaison de la possibilité d'une meilleure vie à l'étranger avec de plus intéressantes perspectives d'emploi et une qualité de vie que je ne pourrais pas trouver en Roumanie » (Ferro, 2004: 96).

Elle circonscrit cette migration entre le recrutement à l'étranger comme seule possibilité de carrière, la remise de fonds pour les familles restées en Roumanie (80 pour cent des émigrés en envoi) et le retour dans un milieu de travail «déprimant» qui gaspille les cerveaux, le capital professionnel acquis à l'étranger sans en profiter aucunement.

D'autre part, nous constatons un grand changement des objectifs des migrants après 2007 : ils ne s'intéressent plus au tourisme culturel, au plaisir de se promener, de voir et connaître d'autres cultures, d'acquérir du savoir-faire et de la compétence professionnelle, mais les jeunes instruits après 2007 sont intéressés par l'argent, ils sont pragmatiques et mercantiles, ils n'ont plus la pudeur de l'argent et du capital. La nouvelle vague est apparue sur le marché du travail.

Dans les programmes d'échanges pour les étudiants comme Erasmus, ils demandent des allocations plus grandes ou refusent les trop petites en récompense de leur travail, ils acceptent de partir à l'étranger seulement parce qu'ils ont des parents qui y travaillent et peuvent faciliter leurs conditions de vie et leur permettre d'épargner de l'argent ou mieux encore s'ils y retrouvent un petit ami ou un/une autre de nouveau/nouvelle, récemment « connu/e » sur les réseaux de socialisation dont ils sont dépendants.

### **3. L'Actualité de la migration**

Elle s'identifie avec les transformations très rapides qui ont caractérisé la dernière décennie. Au gouvernement libéral de Tăriceanu et à l'Alliance Dreptate-Adevăr (Justesse - Vérité) a succédé le gouvernement de Boc, contesté et réinvesti quatre fois par le président Băsescu. Tăriceanu a eu une politique d'encouragement du retour des diplômés des hautes écoles réputées (universités américaines surtout et européennes aussi). Comme il était un continuateur d'Emil Constantinescu qui se vantait d'être soutenu par 15 000 intellectuels et qui s'en est retrouvé seul après certains compromis politiques (soutien des Cossovares contre les Serbes, engagement de troupes sous l'oripeau de l'OTAN), Tăriceanu a fondé 224 agences et régies gouvernementales où il a embauché de jeunes intellectuels formés en Occident, avec des salaires au même niveau, une nouvelle classe de yuppies et lèche-bottes qui ne se laissent plus renverser de leur position privilégiée. Quant au président Băsescu, il s'est toujours positionné contre les intellectuels : à la foire du livre « Bookfest », en 2009, accueilli par le philosophe Gabriel Liiceanu, le directeur de la maison d'édition « Humanitas », ancienne « Editura Politică », il a exprimé une opinion gênante sur la capacité de l'école roumaine à « préparer des stupides, pardon des philosophes - au lieu de produire des ferblantiers, des mécaniciens et des serveurs dont nous en avons vraiment besoin ». Après sa réélection il a dû reconnaître l'existence de la crise et la nécessité de prendre des mesures exagérées contre toute la population : diminution des salaires, imposition de toutes les pensions de retraite et autres mesures impopulaires pour le bas de la hiérarchie. Il a invité les jeunes diplômés à quitter la Roumanie pour se réaliser ailleurs et, de la sorte, aider leur pays :

«Nous devons réformer l'éducation parce qu'elle produit des chômeurs académiciens : trop de philosophes, trop peu d'ingénieurs et ceux qui s'y trouvent n'ont pas les qualifications recherchées» dit-il dans une interview dans le quotidien *Frankfurter Allgemeine Zeitung* (in Leca, 2011) pour signaler l'inadvertance du système au marché.

#### 4. Hypothèses

L'élite technique créée par les communistes pendant la dictature du développement était partie après 1989 à cause de la désindustrialisation forcée. 85% de la population de la Roumanie était pro occidentale traditionnellement: l'élite intellectuelle, les catholiques et les unitariens, les Juifs, les Allemands, les Hongrois et aussi les paysans dépossédés de leurs terres et obligés de travailler au Canal. Par conséquent une hémorragie de la main d'œuvre existait déjà avant l'exhortation du président, l'intellectualité roumaine était déjà en dérive et nous supposons que la jeunesse intellectuelle continue ce processus.

Dans cette recherche, nous sommes parties de l'idée que les étudiants de notre faculté voulaient étudier à l'étranger pour pouvoir y rester et occuper un emploi mieux payé qu'en Roumanie, influencés par les mentalités de leurs parents et confiants dans le mythe du bien-être occidental. Nous avons présupposé que l'étude des langues modernes facilite et favorise leur départ. La maîtrise d'une langue étrangère peut atténuer le choc culturel d'un émigrant et faciliter son insertion dans une société étrangère.

Notre corpus d'étude est basé sur les réponses de 115 étudiants de notre faculté (Faculté d'Economie et d'Administration des Affaires de l'Université de l'Ouest de Timișoara, Roumanie) au questionnaire distribué le 27 avril 2012 et comprenant les rubriques suivantes : la section des données sur le profil du répondant (année d'étude, spécialisation, sexe, âge, milieu) ; la section des opinions sur l'enseignement universitaire et sur les perspectives d'évolution professionnelle ; la section sur les compétences linguistiques.

La plupart des sujets proviennent de la première (56 étudiants – 48,7 %) et de la deuxième année d'étude (44 étudiants – 38,26 %), tandis que la troisième année est moins représentée (15 étudiants – 13,04 %). Nous avons envisagé toutes les spécialisations de notre faculté (comptabilité et gestion, tourisme et services, finances banques, management, marketing, relations économiques internationales, etc.). Les réponses nous ont permis de constater encore une fois que le nombre de jeunes filles est plus grand que celui de jeunes garçons (64,35 % par rapport à 35,65 %) et que les étudiants qui proviennent du milieu urbain (75,66 %) sont beaucoup plus nombreux que ceux qui proviennent du milieu rural (24,34 %). Leur âge est de 19 à 23 ans.

La deuxième section du questionnaire nous a permis de connaître les opinions des étudiants sur les principaux aspects de notre démarche didactique. Nous pouvons constater ainsi un pourcentage de « culpabilité » pour leur départ. La sixième question les interroge sur la satisfaction que les études leur offrent à partir du qualificatif « très content » jusqu'au qualificatif « très mécontent ». En général ils sont contents ou très contents des connaissances théoriques, de la dotation matérielle et IT de notre faculté, de l'adaptation des programmes d'études aux exigences actuelles. Leur mécontentement est lié surtout aux habiletés pratiques acquises pendant leurs études. On a souvent reproché à l'enseignement roumain son caractère trop théorique et, selon les réponses de nos étudiants, il semble que les choses n'ont pas trop changé. Dans une faculté d'administration des affaires les étudiants s'attendent à acquérir plus d'expérience dans le domaine que de connaissances théoriques.

La septième question propose une comparaison entre l'enseignement universitaire roumain et les systèmes occidentaux compte tenu du fait que, même s'ils n'ont pas encore étudié à l'étranger, nos étudiants connaissent les autres offres dans le

domaine car l'Internet les a aidés à se renseigner. La simple comparaison entre plusieurs systèmes d'enseignement universitaire explique la différence entre les réponses à la sixième et les réponses à la septième question où le nombre de ceux qui sont contents et très contents de l'enseignement roumain baisse (26,08 % et 5,22 %) et augmente celui des « indifférents » (25,22 %) et des « mécontents » (20,87 %). Il est à mentionner aussi le nombre assez important de ceux qui n'ont pas répondu à la sixième (22,6 %) et à la septième question (22,6 %) malgré la confidentialité des réponses. Probablement il s'agit du désir ou de la peur de ne pas vexer les professeurs.

Conformément aux réponses à la huitième question, la plupart des étudiants préféreraient faire des études de master à l'étranger (56,52 %) tandis que ceux qui ont opté pour la licence à l'étranger sont moins nombreux (24,35 %) et encore moins nombreux ceux qui aimeraient faire leur doctorat à l'étranger. Dans les discussions que nous avons eues avec nos étudiants, ils ont justifié cette option en disant qu'ils voudraient être plus âgés lors de leur départ à l'étranger et que le master leur laisse plus de temps pour travailler et pour gagner assez d'argent afin de ne pas solliciter l'aide de leurs parents. Le nombre assez réduit de ceux qui ont opté pour le doctorat est lié au fait qu'il y a peu d'étudiants qui veulent faire des études doctorales, qu'ils préfèrent plutôt travailler qu'étudier.

Le nombre de réponses à la neuvième question a constitué une surprise car le pourcentage de ceux qui veulent rester à l'étranger à la fin de leurs études n'est pas beaucoup plus grand que celui de ceux qui veulent revenir en Roumanie : 49,56 % par rapport à 42,6 %. En ce qui concerne les justifications qu'ils ont formulées, la première place est occupée par le niveau de vie plus élevé (19,13%) suivi des opportunités professionnelles (16,52 %) et de la reconnaissance de la valeur individuelle (13,89 %). Il y en a d'autres qui parlent du niveau plus réduit de corruption, des possibilités de développement sur le plan professionnel ou de l'appréciation de l'employeur. Pour ceux qui envisagent la possibilité de revenir, les justifications sont d'ordre économique (opportunités plus nombreuses de lancer une affaire, le potentiel économique de la Roumanie en tant que pays en voie de développement, la mise en pratique des compétences acquises à l'étranger), mais aussi sentimental (les amis et la famille, le désir de changer quelque chose dans la société roumaine et même le patriotisme, un argument – surprise quand il s'agit de la jeune génération qui est plutôt cosmopolite).

Le pourcentage de ceux qui se déclarent « adaptables » à la vie dans une autre culture est presque égal au pourcentage de ceux qui veulent rester à l'étranger (59,13) et à ceux-ci s'ajoutent ceux qui se déclarent « très adaptables » (10,43%). Personne ne se déclare « très inadaptable » et très peu sont ceux qui se reconnaissent « inadaptables » (4,35%). Ces réponses montrent que grand nombre de nos étudiants seraient capables de s'adapter à une autre culture et pourraient vivre à l'étranger. D'ailleurs dans les programmes de mobilités internationales il y a eu très peu d'étudiants qui n'ont pas pu s'adapter à un nouveau style de vie et se sont déclarés incapables de répondre aux exigences des universités étrangères.

La onzième question est la plus importante dans l'économie de notre communication parce qu'elle donne les raisons du retour en Roumanie après les études dans d'autres pays. Elle nous offre à nous, enseignants, les enjeux et les directions d'action pour convaincre les étudiants de revenir pour utiliser leur savoir-faire dans l'environnement économique roumain. Ils sont les contribuables qui payeront les impôts et les taxes ainsi que les pensions de retraite parce que notre système

d'enseignement les a formés et a investi dans leur formation initiale. Dans la première période après 89 nous avons eu un grand nombre d'informaticiens dont presque tous quittaient le pays et les décideurs ont envisagé d'augmenter le nombre d'étudiants en IT juste pour en exporter. Mais l'investissement était trop grand par rapport aux bénéfices et le facteur surprise a été le patriotisme qui revient ces dernières années. Les jeunes gens apprécient les efforts de leurs parents, aiment leurs familles, les coutumes locales, la musique de la jeunesse et les danses redeviennent roumaines et le patriotisme démonétisé par l'excès communiste revient en force et reconquiert parce qu'il n'est plus imposé. On diffuse des CD en roumain avec des chansons patriotiques.

Le problème du salaire est considéré très important par 27,82%, important par 44,38% et neutre par 13,91% et les rubriques «peu important» et «sans importance» n'ont pas de répondants, ce qui reflète l'intérêt accru pour l'argent, justifié par la pauvreté quasi générale de nos étudiants. Ils travaillent à temps plein pour payer leurs études et leur vie et ont parfois plusieurs emplois parce qu'ils sont mal payés et n'arrivent pas à pourvoir à leurs besoins. Ils seront déjà fatigués avant d'entrer sur le marché du travail.

L'acquisition de nouvelles connaissances de spécialité selon le profil professionnel est considérée très importante par 22,6 %, importante par 38,26 %, ce qui dépasse la moitié des répondants, mais elle est considérée indifférente par 17,39 % et peu importante par 12,17 %, soit 29,56 % – un tiers – qui n'accordent plus de l'importance à la qualité des connaissances, du savoir professionnel dispensé dans le milieu universitaire. On peut présumer qu'ils n'ont plus confiance à la justesse de l'évaluation et de la prise en compte du critère par l'environnement socio-économique où les patrons et les employeurs ont des évaluations plutôt subjectives et le « capital social » s'avère plus important que le savoir professionnel.

La vérification de cette affirmation se fait par les réponses au troisième critère, à savoir le gain de respect proportionnellement aux connaissances acquises et aux valeurs promues. 31,3 % constatent que le critère est très important, 33,04 % croient qu'il est important (64,34 %) tandis que 15,65 % le trouvent indifférent et 10,43 %, peu important (soit 26,18 %). Un quart des répondants manifestent du cynisme et nous tirons cette conclusion parce que dans la rubrique où l'on demande de proposer d'autres critères, ils ne proposent rien, donc ils n'ont pas d'autres valeurs alternatives.

Le développement des perspectives d'évolution professionnelle se rapproche des deux derniers critères par les résultats : « très important » 29,56 %, « important » 34,78 % (un total de 64,34% d'optimistes qui ont confiance dans l'évolution de leur carrière professionnelle dans notre pays). La Roumanie reprendra la croissance économique et offrira plus de conditions de développement que tout autre pays occidental parce qu'ici tout est à faire. Les «indifférents» (13,04 %) et ceux qui ne répondent pas (22,6 %) ne croient pas à leur évolution professionnelle en Roumanie et acceptent n'importe quel emploi pourvu qu'ils touchent au moins le SMIC.

Le dernier aspect évalué, celui des facilités (logement, voiture, téléphone, ordinateur, etc.) assurées aux jeunes diplômés par les employeurs est apprécié par une majorité de 65,48 % (26,95 % «très important» et 39,13 % «important») des répondants, ce qui vérifie le manque de moyens matériels. Pour ces jeunes un logement est un rêve inaccessible vu les prix dans l'immobilier et le niveau des salaires. La voiture accessible au diplômé est «second hand». Même un portable plus cher et plus performant est peu accessible pour lui. Il n'y a que 16,52 % des

sujets qui se déclarent «indifférents» et 13,04 % qui considèrent ce critère «peu important» parce que ce type de facilités ne concerne pas leur emploi ou mieux, ils les possèdent déjà.

Les trois dernières questions (12. Mentionnez la langue moderne étudiée à la faculté, 13. Quelles autres langues étrangères connaissez-vous ? et 14. Quelle est votre langue maternelle ?) nous ont permis de constater que les répondants qui étudient l'anglais à la faculté (58,26%) sont plus nombreux que ceux qui étudient le français (23,48%) ou l'allemand (16,52%). La plupart des sujets ont déclaré qu'ils parlent au moins deux langues étrangères, principalement l'anglais et le français, mais aussi l'allemand, l'espagnol, l'italien et le hongrois. Selon les résultats aux questions 12 et 13, nous avons constaté que, du point de vue linguistique, au moins, nos étudiants sont facilement adaptables à la vie dans un autre pays, qu'ils sont capables de communiquer avec les autres citoyens de l'Europe. Les réponses à la dernière question reflètent la composition ethnique de la population de notre région (87,82% Roumains, 4,35% Magyars, 1,74% Allemands et 3,48% Serbes). Il est à remarquer que l'ethnie ne joue aucun rôle dans les options exprimées par nos étudiants et que leur mécontentement a les mêmes causes.

## 5. Conclusions

Tous ces résultats montrent que notre université doit continuer de développer le côté pratique de ses activités et qu'elle doit encourager les programmes par lesquels ce stage est payé (PRAXIS et PracTeam sont les deux programmes implantés dans notre faculté). Depuis deux ans on a trouvé des banques surtout, mais aussi d'autres entreprises (en fonction de la spécialisation des étudiants) qui reçoivent de la part de l'Etat les fonds nécessaires pour payer les stages. On a enfin compris que le stage n'était pas une simple formalité, comme avant l'introduction des programmes susmentionnés, qu'il avait une contribution importante à la formation des étudiants de notre faculté.

Une autre mesure qui pourrait encourager les étudiants à retourner dans leur pays serait la création d'emplois dans notre institution. Ainsi gagneront-ils l'argent nécessaire et l'expérience exigée par les employeurs : de la cafétéria à la bibliothèque on pourrait réserver tous les emplois aux étudiants.

Ces mesures proposées à l'intérieur de notre faculté doivent être réglées et soutenues par l'élaboration des normes d'application des lois, car les lois, elles existent déjà. Il faut dépasser la dictature actuelle des administrations incapables de créer des emplois pour les jeunes et de les motiver à rester en Roumanie.

# DYNAMICS OF CHANGES IN ROMANIA KNOWLEDGE ECONOMY

**Burja Camelia**

*University „1 Decembrie 1918” of Alba Iulia, Faculty of Sciences, Romania  
cameliaburja@yahoo.com*

**Abstract:** *By joining the European Union, the new member states have benefited from more opportunities for interaction and knowledge transfer, which boosted the transition to the knowledge economy. This paper deals with three areas that are the drivers of KE, education, research-development-innovation and information for a selection of European countries, which are the new EU member states (NMS). It focuses on identifying the current state of growth performance in Romanian economy in relation to some of the relevant KE indicators, the main tendencies manifested in the last years and their contribution to the KE development within the EU's developing countries group. The findings of the research reveal that the Romanian economy performance in KE terms has registered a positive dynamism, but this country is not on the efficiency frontier yet, being closer rather to the middle level of development from the new EU member states.*

**Keywords:** *Data envelopment Analysis, Knowledge economy, Economic growth, Economic performance*

**JEL classification:** *I25; O11*

## 1. Introduction

Over the last years, the economic growth in Europe has been reduced with some noticeable differences of competitiveness compared to other regions of the world (Nijkamp and Siedschlag, 2011). In order to surpass this situation, the Lisbon Strategy (2000) recommended to the EU countries to create a stimulating framework based on knowledge and innovation aimed at improvement of competitiveness and economic growth, and at enabling the transition to knowledge-based economies.

Countries that later joined the EU including Romania have adopted the European economic-social model of development and strived to approach the features of advanced countries, in which the Knowledge Economy (KE) is already a reality.

This paper has as objective to analyze the progress made by Romania to develop an economy based on knowledge. In a Knowledge Economy the economic growth is closely linked to knowledge production and its utilisation with higher efficiency in the entire society (Karagiannis, 2007).

The study aims to answer some questions, such as: What is the present stage of KE within the countries that joined the EU later? What are the trends related to the specific areas of KE in these countries and in Romania?

For answering these questions, the research is carried out in the following stages: selection of main specific indicators for domains related to the KE in EU's NMS (importance, availability of data, statistic significance); assessment of KE pillars performance in each country of the group and on the assembly; comparative analysis of the efficiency scores for KE pillars in Romania in comparison to countries which are on the efficiency frontier and to the average score of the overall selected countries.

The research method used is Data Envelopment Analysis (DEA). For selected countries, the efficiency analysis models depending on education, research-development and ICT (information and communication technologies) have been estimated. These components are considered the key factors to boost the economic growth in KE terms. The efficiency frontier identified allows appreciating the relative performance gaps between each country and the group leaders, and formulating some future action directions.

For Romania, the results indicate a greater contribution to growth of the KE drivers compared to the moment of accession. But the relative performance of each KE component is low.

Reducing development gaps between the country and the other EU members, and accelerating the transition to knowledge economy will only be possible by implementing some coherent policies to stimulate especially innovation and investments in human capital.

## **2. Literature review**

After the middle of the twentieth century the growth theories considered that long-run economic growth could not be explained only by the capital accumulation. Arrow (1962) introduced the idea that through learning, labour force can accumulate experience, increase productivity and accelerate the economic growth. The studies of Romer (1986) and Lucas (1988) also pointed out the prominent role of human capital, and that a stable growth rate can result by accumulation of knowledge. More recently literature has analyzed the knowledge based economy pattern. In this economy, knowledge is regarded as main element of development process, ensuring high economic growth and opportunities for social progress (Chen and Dahlman, 2005).

The studies performed by the World Bank reveal that a strong relationship exists between knowledge accumulation and economic development. The higher the knowledge stock is (measured by Knowledge Economy Index), the greater the level of the countries' economic development is (World Bank, 2012a).

The Lisbon Strategy stated that the Knowledge-based Economy should be the priority direction for progress and economic development in Europe. Stimulating the knowledge creation and utilization in every domain aimed for Europe to improve the economic, social and environmental performance in the next decade, in order to transform in the most competitive region in the world with a sustainable economic development.

Changing an economy into a Knowledge-based economy requires some actions, such as radical transformation of Information and Communication Technologies system, enhancing the research and development sector, increasing of the competitiveness, consumption and incomes, orientation to quality (Coates and Warwick, 1999).

Recent studies concerning the world's regions or countries, analyzed the Knowledge-based Economy according to elements such as R&D effort, quality of human resources, innovation capacity, IT diffusion, access to finance and information society (Karagianis, 2007), sustained investments in education, innovation, information and communication technologies, and a conducive economic and institutional environment ((Chen and Dahlman, 2005), human capital, innovation ability, information access (Nijkamp and Siedschlag, 2011), industry R&D, venture capital, workforce education, fast growth firms (Watkins, 2008), knowledge workers

(ICT sensitivity, educational level, creative class and communicative skills), R&D and innovativeness (Westeren, 2012).

To create an unique framework and ease the evaluation of a country's progress towards the Knowledge Economy, the World Bank has developed the Knowledge Assessment Methodology (Chen and Dahlman, 2005; World Bank, 2012a). According to it, the countries' readiness for the Knowledge Economy is appreciated based on numerous indicators which are synthesised by four pillars: economic and institutional regime, education and skills of population, information infrastructure and innovation system.

Also, in Romanian specific literature the interest for Knowledge Economy is perceived. The studies concern various theoretical aspects related to KE and its perception by companies (Ceptureanu et al., 2012), assessment of ICT indicators contribution to KE using World Bank methodology (Goschin and Constantin, 2007), constrains in innovation implementation (Brătianu and Vasilache, 2009), relation with sustainable development etc. This present study intends to evaluate the advances of Romanian economy towards KE after joining the EU, in a comparative manner against the other developing countries of the European Union using a nonparametric method. The advantage of this approach is that one can have a synthesis picture of how effective the country uses its internal resources to generate knowledge and economic value.

### 3. Methodology

In this study, the performance and trends assessment of the KE drivers is performed using Data Envelopment Analysis (DEA) approach. DEA is a nonparametric method by which a linear programming model is built based on some empirical outputs and inputs for a number of decisional units.

Resolving the model leads to identification of an efficiency frontier on which the most performing states are positioned (efficiency score is 1), all the other countries that have efficiency score less than 1 being considered inefficient. The performance scores obtained allow both ranking of the decisional units (countries) according to their relative individual performance, which depends on the conditions and variables specified, as well as pointing out the ways to increase efficiency.

In this paper, the CRS (constant returns to scale) output oriented model proposed by Charnes, Cooper, and Rhodes (1978) and the ratio form of data as suggested by Coelli et al. (2005) were used. This model considers  $k$  decisional units, each of them with  $n$  inputs and  $m$  outputs.

The efficiency for the decisional unit  $k$  is as follows:

$$E_k = \frac{\sum_{j=1}^m v_j y_{kj}}{\sum_{i=1}^n u_i x_{ki}} \quad \text{s.t.} \quad \frac{\sum_{j=1}^m v_j y_{kj}}{\sum_{i=1}^n u_i x_{ki}} \leq 1 \quad ; \quad \forall u_i, v_i \geq 0$$

in which:  $u_i$  represent weights of inputs;  $v_j$  represent weights of outputs variables.

Data are for period 2007-2011 and aim the main aspects of production, use and dissemination of knowledge in the new EU member states: Czech Republic (CZ), Estonia (EE), Cyprus (CY), Latvia (LV), Lithuania (LT), Hungary (HU), Malta (MT), Poland (PL), Slovenia (SL), Slovakia (SK), Bulgaria (BG) and Romania (RO).

In order to analyze their possible economic growth driven by knowledge capacity, indicators were used from domains known as key sources for boosting development, namely human capacity, innovation ability and information access (Nijkamp and Siedschlag, 2011; World Bank, 2012a). The representative indicators have been selected according to the results of some previous researches concerning the determinant factors of economies based on knowledge and provided by the EU statistics: "Education and training", "Science, technology and innovation" and "Information society". The "Gross Domestic Product at market prices per capita" (GDP) was used to appreciate the economic performance because its level expresses the returns from investments in knowledge factors made by a country.

#### 4. Results and discussions

The assessment of challenges in Romania Knowledge Economy was performed with Data Envelopment Analysis techniques considering the three pillars that can stimulate growth and development. To identify the country's progresses to an economy based on knowledge, comparisons with the other new EU member states have been made for two time periods, namely 2007 (when Romania joined the EU) and 2010 (most recent year with complete information in databases).

A). The education system has a major contribution to the increase of the stock of global knowledge by which a country can more rapidly advance towards KE. The indicators used to evaluate the impact of education on KE were selected according to their potential to boost the innovation process and knowledge transfer (Table 1).

**Table 1:** Indicators of knowledge economy on education

Country	GDP per inhabitant		Participation rates in education, %		GMST per 1000		Public expenditure on education	
	2007	2010	2007	2010	2007	2010	2007	2009

Indicators from Table 1 contain some empirical observations of outputs and inputs for the envelopment problem solved by DEA technique. The output is represented

by the indicator „GDP at market price, PPS per inhabitant” and inputs are the variables: „Participation rates in education (students aged 15-24 years as % of corresponding age population)”, „Graduates in mathematics, science and technology per 1000 of population aged 20-29 years” (GMST) and „Total public expenditure on education as % of total public expenditure, for all levels of education combined”. Although there are other important indicators in knowledge creation and dissemination (i.e. language learning), the missing data for some countries has led to restriction of the number of indicators used in analysis.

The model was solved in CRS version and output-oriented version and the results obtained are in Table 2.

Czech Republic, Cyprus and Malta are countries that took advantage of education system in growth. Romania presented a positive trend of its relative efficiency score (4%) but this is still reduced in comparison to the scores of group leaders and even to the average level of the indicator, being classified as inefficient. The study of the indicators (Table 1) to determine the performance of the education system highlighted that there are not major differences of indicators in Romania against the countries on the efficiency frontier. In Romania (2010), the number of persons enrolled in secondary and tertiary education (15-24 years) is higher with 18% than of Cyprus and Malta. Graduates from the mathematics, science and technology fields are 3 times numerous than in Cyprus and 2 times more than of Malta. Also, the levels of these indicators are closely to those of Czech Republic. However, the Romanian education system has 41% lower efficiency than that of the other countries, meaning that its labour force did not sufficiently contribute to value creation within the economy.

One of the causes for which the knowledge acquired in schools did not have the expected effects in Romania’s economic growth is unbalanced situation between knowledge and labour market demands. In Romania in 2009, the share of registered unemployed people under 29 years in the total unemployed persons was 24.2%

(N.I.S., p.114, 2010). Another cause for lower contribution of knowledge acquired by young people to the GDP formation is the phenomenon of their emigration to other countries. Thereby at the end of 2009, of the total persons who settled their permanent residence abroad, about 25.3% were under 25 years, and 52.3% of emigrants were 26-40 years (N.I.S., p. 79, 2010).

B). For determining the contribution of R&D factors to a better preparation for transitioning to Knowledge Economy for the EU new member states including Romania, the GDP (v. Table 2) and the indicators presented in Table 3 have been considered.

In the second DEA problem, the relevant inputs for identifying the technical and economic development potential of business environment are: „Business enterprise R&D expenditure”, „Human resources in science and technology” (25-64 years, % of active population) and “Enterprises with innovation activity” (product, process, ongoing or abandoned, organizational and marketing innovation), and output variable is GDP per inhabitant.

The comparison between countries in terms of their relative performance of their R&D system towards KE identified for 2010 Cyprus, Malta and Poland on the efficiency frontier (Table 4). All the other countries had in comparison to them a lower efficiency of the research and innovation process.

Romania had an relative efficiency score with 21.5% lower than the group leaders, situation which can be explained by the existence of a more reduce capacity to produce and apply innovative knowledge, therefore this direction seems to be a reserve to increase the performance. In the world ranking on economies competitiveness made by the World Economic Forum, Romania also has a low score for the innovative capacity (3.2 on 1 to 7 scale) (Schwab, 2012).

Source: DEAP soft

The assessment of developing countries based on the efficiency of their ICT sector recorded in 2010, ranked Romania on the second last place in the group of 12 states, with a relative score of 0.83. In the hierarchy made by the World Economic Forum based on the Networked Readiness Index 2012, it was ranked 67<sup>th</sup> out of 142 countries with a score of 3.9 (1 to 7 scale); among the EU countries it ranked ahead only of Bulgaria (Dutta and Bilbao-Osorio, 2012).

Although, the ICT has increased the contribution to economic growth with 14.6% compared to 2007, Romania, with an efficiency score lower with 17% than Lithuania and Slovenia, is still below the average level of efficiency in the group of EU's NMS.

**Figure 1:** Evolution of relative performances of KE drivers in Romania

According to Figure 1, in Romania there was an improvement of the performance score of the education system with about 8%, but it is much lower than the average level of new EU member states. In this sector, some adequate strategies for increasing the share of enrolments in education, stimulating professional training for high-tech activities and better financing are required.

The efficiency trend of resources used for knowledge creation and utilization by R&D sector was also positive, but its relative increase was higher only with 3% in comparison with the accession year. In order to reduce the performance gap against other countries, the rhythm of innovation should be intensified. This action implies more investments in research-development activities, increasing the share of labour force that works in this area and extending application of research results in production. There are some consistent results from investments in information infrastructure, which contributed to the increase of performance with 14.6%. Extending the ICT technologies within enterprises allowed knowledge dissemination and utilisation on a large scale and a higher contribution to value creation in the national economy. For the future, development of the information society will remain an important direction to stimulate the economy based on knowledge.

Results of the analysis undertaken are consistent with recommendations made by the World Bank. In Romania, in order to accelerate the participation of knowledge disadvantaged communities in the Knowledge-based Economy, it is necessary to develop areas such as education, innovation support for enterprises, businesses and public communications with the Government, the financial self-services, e-commerce (World Bank, 2012b).

## **5. Conclusions**

Among the countries that later joined the EU, there are some disparities in utilisation of the resources that are specific to the Knowledge Economy. The Data Envelopment Analysis technique has been applied to determine the efficiency of educational factors, elements of R&D, and ICT factors in correlation to the GDP, and the relative performance scores for each KE pillars were obtained. The efficiency frontier separates the analyzed countries in two groups: efficient countries – those with maximum performance scores and inefficient countries – other countries, which have lower scores than efficient ones. For all of the pillars Romania belongs to the group of inefficient countries.

Due to the differences of economic growth between Romania and the other new EU member states, it ranked in a modest position, with important implications for the quality of population's life. However, compared to the moment of accession, Romania has registered some progresses in KE terms.

The area where less progress has been made compared to other countries is education. Although at the national level, educational factors contributing to the GDP increased significantly, in relative terms their performance remains quite low and somehow, justified. The structural changes of economy caused by the accession in the EU led to emergence of some uncontrollable phenomena (migration of population being only one of them), the economic effects of investments in people not being present in totality in the country. Another cause is insufficient funding of the sector infrastructure.

Increasing the competitiveness and dynamism of the Romanian economy requires effective policies to be designed. They should address the measures of increasing the internal resource performance, especially in areas that can generate knowledge and innovation, and should continue to benefit from the ICT growth potential.

# EXTERNAL FACTORS FOR THE MONETARY POLICY TRANSMISSION MECHANISM

**Dan Horațiu**

*Economics and International Business Department, The Faculty of Economics and Business Administration, Babes-Bolyai University, Cluj-Napoca, Romania  
dan.horatiu.sorin@gmail.com*

**Abstract:** *This paper reviews and analyzes the effects that external (or exogenous) factors, defined as economic factors that cannot be controlled or influenced by the central bank, have on monetary policy and the monetary policy transmission mechanism. Adopting a theoretical research position, we aim at identifying the main external factors to monetary policy and discuss the ways in which these factors alter the economic environment and implicitly the monetary policy transmission mechanism. This is done by changing the way in which monetary transmission channels work and deliver monetary policy decisions throughout the economy, with the final goal of producing central bank desired outcomes with regard to economic variables like inflation, employment, or the production level. We will begin this article with a brief introduction on the topic of monetary policy, the monetary policy transmission mechanism and the potential external factors that may influence the monetary policy and the functioning of its transmission mechanism. The main external factors are identified as linked to fiscal policy, commodity prices, financial market volatility or other globalization related processes. After this introduction, we will proceed with the analysis of the nature and influences of each of the above mentioned external factors on monetary policy and its transmission, identifying the potential ways in which they can change the structure and internal processes of the transmission channels. As we will see in the study and highlight in our conclusion, the external factors cause decisive changes in the way monetary policy is transmitted, and thus will strongly influence the decisions that central banks take in order to alter key economic variables. The profound understanding of how these non-central bank controlled factors influence the monetary policy transmission mechanism is a key requirement for central banks, as only by being able to predict, recognize and evaluate the effects of current or future external factors can they succeed in reaching their monetary policy objectives.*

**Keywords:** external factors; monetary transmission.

**JEL classification:** E52; E59.

## 1. Introduction

According to Taylor (1995: 11), the monetary policy transmission mechanism is defined as the process through which monetary policy decisions are transmitted, with effects on the real gross domestic product and inflation. A more detailed definition is given by Ireland (2005: 1). He regards the transmission mechanism as describing "how policy-induced changes in the nominal money stock or the short-term nominal interest rate impact real variables such as aggregate output and employment",

adding that "specific channels of monetary transmission operate through the effects that monetary policy has on interest rates, exchange rates, equity and real estate prices, bank lending, and firm balance sheets". The European Central Bank's observation completes the picture: "The transmission mechanism is characterized by long, variable and uncertain time lags. Thus it is difficult to predict the precise effect of monetary policy actions on the economy and price level."

Besides the endogenous elements composing the monetary policy transmission mechanism and its five channels: the expectations channel, the interest rate channel, the asset price channel, the credit channel and the exchange rate channel (Loayza, Schmidt-Hebbel, 2002: 4-6), elements which we call endogenous because they can be controlled directly by the central bank, there are also factors that influence the monetary transmission. We will refer to these factors as being external, or exogenous, in the sense that they fall out of the central bank's control area, so that their perturbances in the way monetary transmission functions can't be tackled directly. Instead, the central bank must learn to identify these factors, predict their occurrence and evaluate the changes brought in the transmission mechanism, so that it may adapt its monetary policy decisions to the new environment.

According to Gokarn and Singh (2011), central banks need to pay special attention to the external factors affecting the transmission channels dealing with exchange rates, credit and asset prices and evaluate the consequences of changes in the structure of these channels on production levels and price and financial stability. It is a view that we adhere to, as these channels are most exposed to the global economy and to globally formed market prices, which can induce channel structural changes that may become real obstacles in the central bank's mission.

External factors are of many types and often difficult to predict. This may prove to be a problem, as external factors have the capacity to bring upon major changes in the socio-economic climate. The most pertinent example is that of the 2007 subprime crisis, which shortly developed into a worldwide crisis, affecting virtually all aspects of the economic life, determining the deterioration of world economic indicators and forcing central banks from all over the globe to adopt a different, sometimes unprecedented, strategy regarding monetary policy as they were trying to revitalize the economy and bring growth and employment back on track without forgetting about the inflation targets.

We can identify a whole series of exogenous factors that can have major influences on the way in which monetary transmission mechanisms work. Our goal however is not to generate an exhaustive list of such factors, as this list would be both very long and constantly changing due to the processes of metamorphosis that take place all the time in the economic climate. Instead, our aim is to identify and analyze the main such factors, which, besides having the biggest probability of occurrence, also illustrate a general pattern of change induction that might be relevant to the effects of other exogenous elements that may influence the economy and the transmission mechanism at a given time. Bearing this in mind, we will continue by naming these main external factors:

- commodity prices
- changes in global economy, correlated with the continuation and acceleration of the globalization process
- volatility of financial markets
- fiscal policy.

The next pages will be dedicated to analyzing each of these factors and identifying the processes through which they are influencing the general economic environment and the monetary policy transmission mechanism.

## **2. Commodity Prices**

The changes in commodity prices represent an important external factor, with a high disruptive potential on the transmission mechanism channels, especially the asset price channel. In order to be as clear as possible, we are referring to the commodities whose prices are either established on the global market, or present a high degree of correlation with it when formed locally and which are consistent with at least one of the following criteria:

- they represent important enough raw materials for products and services produced or consumed internally so that price fluctuations will reflect in the inflation level
- have a weight in the commercial balance that is big enough to have their price changes determine commercial balance fluctuation.

We need to underline the aspects regarding the changes in commodity prices and their impact on the economic climate in general and the inflation level in particular, as shocks in commodity prices represent, together with fluctuations in exchange rates due to external causes, the main gateway through which exogenous factors influence inflation (Gokarn and Singh; 2011).

Placing ourselves in the first determinant scenario outlined above, we observe that the commodity price level has, in the first place, a direct impact on production costs, eventually reflecting itself in the production level and finished goods prices through the demand and offer mechanism. So, a positive evolution of commodity prices contributes, with an intensity depending on the elasticities of demand and offer, to the diminishing of production and growth of inflation.

In the second case and in the absence of the validity of the first scenario which was already discussed, the economy is a net exporter of that particular commodity or derived goods, which means that it is sensitive to the capital flows resulting from the transaction. The size and variation of these flows have an impact on inflation through the rise of disposable income. Also, a long period in which such flows exist may favor the development of bubbles within the economy which, if followed by a sudden drop in international prices (which means a drop in capital flows generated by exports), may burst, creating instability and making it a lot harder for the central bank to reach its macroeconomic objectives.

Another way in which changes in commodity prices influence unemployment and inflation lies in the propagation mechanism of this kind of shock. More precisely, a change in commodity prices influences the natural rate of unemployment, which is in fact the rate of unemployment required to keep a steady inflation rate (Rissman, 1986: 3). For a better understanding of the dynamics of this process, we will focus on a clear example, let's say a sudden rise in the price of oil. This will determine the natural rate of unemployment to rise, under the pressure of two factors. First, a superior oil price has effects on raising the production costs for different products, determining the producer to try to compensate, at least partially, by lowering costs with labor. On the other hand, real expenses of consumers rise, as does the level of production due to the interaction of demand and offer (Bessinger, 2001: 3-4). From here to inflation there is only one step left, given by the expectations augmented

Phillips Curve. According to the theory, "the change in the inflation rate depends on the difference between the actual and the natural unemployment rates. When the actual unemployment rate is higher than the natural unemployment rate, the inflation rate decreases; when the actual unemployment rate is lower than the natural unemployment rate, the inflation rate increases." (Blanchard, 2006). The relationship is however valid only in the short-term (Phelps, 1969). So, in conclusion, a sudden rise in oil price will put pressure on inflation only in the short run. Sufficiently however to create economic perturbances.

### **3. Financial Globalization and Monetary Policy**

Financial globalization is a long-term process, very difficult to reverse and, most importantly, in a continuous state of evolution. Bearing this in mind, the influence that financial globalization has on monetary policy and the structure of its transmission mechanism can prove to be a real challenge for central banks and their need for control. This however does not mean that financial globalization is always a bad thing from a central bank point of view, just that it alters the rules of the monetary policy game and makes it much more complex.

The process of financial globalization is probably one of the most visible effects of the decisions and economic architecture inspired by neoliberal principles and it is characterized by a complex series of elements. Out of these, the most important are the ones regarding changes in both public and private sector through easy access to capital, which, more than ever, became a „global good” and the ones concerning the process of integration in the banking system, which, in the broader context of deregulation, has become a catalyst for development with little or no obstruction from national borders. Taking a complementary view on all these, Bădulescu (2007) identifies three components of financial globalization: compartmentation of markets, financial deregulation and de-intermediation. On the same subject, Aglietta (1999) writes that financial globalization is associated with transformations which have affected the functioning principles of finance and that these transformations are closely connected with the liberalization of national financial systems and international integration.

Financial globalization is, without any doubt, among the economic realities that have dominated the world macroeconomic environment after the Second World War until today. Formally enounced as one of the ten points of the Washington Consensus (Williamson, 1989), a set of economic prescriptions which basically summarize the neoliberal economic approach, and omnipresent in the economic policy promoted in the last decades, the objective of financial globalization seems to have been reached. However, one can argue that the economic effects have not been entirely the ones hoped for. In a global society based on the profoundly human desire of expansion, financial globalization is combining forces with financial deregulation and a high degree of financialization, term used to describe the process of translating different aspects of production and economic activity into market-traded financial instruments, often very esoteric in nature. In this context, the highly mobile and, due to leverage and derivative financial instruments, highly expandable capital, has created the largest bubble in history, with effects on all economic agents, from households to banks, private companies and sovereign states. The overwhelming majority of the world's economies are part of a global financial market which functions based on a cumulus of factors, most of them

external to each individual economy. This modifies the individual national economic behavior, seeking adaptation to a given supra-national environment.

In a critic note towards the neoliberal views that have dominated economic decisions in the last fifty years, Subbarao (2012) makes a clear distinction between what he calls financial liberalization, associated with the financial globalization promoted by neoliberals, and commercial liberalization. He argues that, while the latter is beneficial to all parties involved, the former may prove itself to be very dangerous due to the fact that it makes economies more fragile and increases their exposure to considerable epidemic risk, as has economic history shown so many times. On a more conservative tone, Bernanke (2007) states that even though „globalization has not materially affected the ability of the Federal Reserve to influence financial conditions in the United States, nor has it led to significant changes in the process which determines the U.S. inflation rate, (...) effective monetary policy making now requires taking into account a diverse set of global influences, many of which are not yet fully understood”.

Having these in mind, it's worth mentioning that in 2007 The Federal Reserve Bank of Dallas created a special department whose task is to study the effects of globalization on monetary policy in an open economy, seeking to achieve a greater understanding of the way in which world financial integration influences the American macroeconomic climate.

In this context, the high degree of financial globalization plays a key part in the way that each central bank elaborates its monetary policy, as the overall impact of external factors on the economy and the monetary policy transmission mechanism is strengthened, while in the same time it becomes more interconnected with transmission mechanisms and policy decisions of other monetary areas. In this way, variables like interest rates for other currencies or global financial market prices become crucial elements that the central bank needs to take into consideration when designing its monetary policy, even if they are external to the economy in which the central bank operates. In conclusion, the less important the economy in which a given central bank operates, the less internal control does it have. This happens because, due to financial globalization, the exogenous pressures are relatively higher. Also, this is correlated with the fact that in this case, the central banks' own actions do not constitute important exogenous elements from an international point of view and thus have little influence on the international economic environment. As a result, the central bank is being often forced to shift its actions from a constructive approach to one that constitutes a reaction to external developments. This theory is confirmed by a series of studies which demonstrate the force that monetary policy decisions and transmission mechanism functioning of large economies have over smaller economies, interfering directly with their monetary transmission and affecting their economic variables, as their national bank has little to do about this. From the studies on this subject, we point out those of Awad and Goodwin (1998), Bremnes, Gjerde and Saettem (2001), or Bayoumi and Switston (2007). They conclude that the movements in US interest rates have a greater effect on interest rates in other advanced economies than the changes in the interest rates of those economies have over the indicators in the USA. Also, Ehrmann, Fratzscher and Rigobon (2005) show that, under the pressure of globalization, the intensity of mutual shocks in interest rates between the USA and the Euro Zone have risen, while Ehrmann and Fratzscher (2006) reached the conclusion that non-US market stock prices react to the Federal Open Market Committee (the organism within the US Federal Reserve

that is responsible with open market operations, minimum reserve requirements levels and standing facilities) announcements. Not surprisingly, they also found out that the intensity of these reactions is positively correlated with the level of openness of that particular economy.

Things look in a similar fashion when it comes to the effects of the high degree of banking integration exhibited by the world economy, a phenomenon that alters the functioning of the credit channel within the monetary policy transmission mechanism and thus undermines the control that the central bank has over the economic variables. This is confirmed also by the study of Cetorelli and Goldberg (2009). They point out that, in 2006, more than 65% of the total bank assets were held by banks having a global orientation, a proportion that has been continuously increasing since 1980. In this context, they study banks that have headquarters in the USA and conclude that these global financial institutions create their own internal micro-markets between the central headquarters and the foreign subsidiaries, which implicitly means that they have their own transmission channels. This fact grants them a high degree of independence from the central bank's actions, as they are able to manage capital flows between headquarters and different foreign subsidiaries as a response to monetary policy decisions. The effects of this structure are dual: internally the monetary policy transmission mechanism is weakened; externally, it favors the propagation of monetary shocks generated by the Fed, which act as external factors. Even if it centers on US based global banks, the conclusions of the study can easily be extended to a global level, dividing the world's open market economies in two categories: the ones which have an expansionist banking system, with subsidiaries and holdings at an international level, and those which have their banks dominated or controlled by foreign ones. And as we have already seen, this has a great impact on weakening central bank control over its own economy in both types of monetary zones.

For the picture to be complete, the monetary and financial environment is becoming more and more subject to extreme volatility, a situation which questions neoliberal concepts like rationality of economic agents and market efficiency. We can best illustrate this by taking a look at the high volume foreign exchange (Forex) market. Theoretically, high volumes should provide protection against volatility as there are no players big enough to influence prices by means of market transactions. Practically however, the Forex market is subject to high volatility, a phenomenon that, in our opinion, cannot be explained by looking at the currency fundamentals, but is a direct consequence of psychological factors and speculative objectives, thus providing a clear proof that markets don't function as smoothly or as efficient as neoliberal thinkers would argue.

#### **4. Financial Market Volatility**

High financial market volatility is one of the main factors outside the central bank's control that influence monetary transmission, as financial markets are one of its crucial components, having strong effects mainly on the asset price, credit and exchange rate channels. Also, a high level of volatility augments the influence on the economy of other external factors, like the commodity prices, via volatility on Forex markets. But before going any further, let us clarify what we mean by financial market volatility. According to Kotze (2005: 1-2), the term describes a series of prices or economic variables that are frequently subject to change and wide balances. It

actually measures the dispersion around a central tendency, being a measure of changes in price. Let us now briefly turn our attention to the notion of financial market, which we define as a market where financial instruments are traded. According to the International Accounting Standard 32 (2013: A879), "A financial instrument is any contract that gives rise to a financial asset of one entity and a financial liability or equity instrument of another entity". Mishkin and Eakins (2006: 3-8) name each type of financial markets: the money market, the stock market, the bond market, the mortgage market, the foreign exchange market, the money market and the international financial system. Returning to the subject of financial market volatility from a central bank point of view, even though sometimes central banks have the possibility to intervene on the markets and smooth out some of the volatility, we will still regard volatility as an external factor because these kind of actions performed by the central bank are both expensive and strongly limited in their application methodology, effectiveness and efficiency.

In a market environment characterized by high volatility, the functioning of monetary policy transmission channels is altered, as the effects of monetary policy decisions on financial market prices, which constitute important drivers of transmission through the asset price, credit and exchange rate channels, are relatively smaller. In other words, financial market volatility either attenuates or augments the central bank's actions and thus alters its ability to control macroeconomic variables like employment, production or inflation.

## **5. Fiscal Policy**

Alongside with market volatility and changes in global economy and commodity prices, which have an extended geographical impact, there are also factors that operate at a local level. Out of these, the most important one is represented by the changes in fiscal policy and the impact of taxation and public spending on production levels, unemployment and inflation.

First of all, we need to underline the role that taxes play in the government made budget, as they constitute (one of) the main sources of income. So, at a constant level of public spending, there is a clear relationship between the taxation levels and the budget deficit (or surplus), as raising taxes will lower the deficit (or raise surplus) and, vice versa, lowering taxes will raise the budget deficit (or lower the surplus). More concretely, let's take the case of a lowering in taxation, which, according to Blanchard (2006: 553-572) will have effects on short, medium and long-term, as following:

- on the short run, because of the extra sums available to consumers and other economic agents, the consumption will rise, which will lead to a rise in the production level
- on the medium run, the production level remains unchanged. There are however consequences regarding the interest rate, which will be higher, and on new investments, which will be lower
- on the long run, the production level drops because of the higher budget deficit which will put pressure on capital accumulations.

The effects that the fiscal policy has on the monetary policy transmission mechanisms can be of a disruptive nature, but they can also be complementary to monetary policy. In this context, the lack of correlation between fiscal and monetary policy, the former controlled politically and the latter by an independent central bank,

can lead to suboptimal economic outcomes. On the other hand however, a commonly elaborated strategy can ensure that national budgets are created in such a way that they contribute to the uniformization of economic fluctuations and thus providing an improved transmission of monetary policy actions. Friedman (2008: 53) even states that intermediary monetary policy objectives regarding consumption and investment levels can't be reached without a high correlation between fiscal and monetary decisions. We subscribe to this view, as we also hold as crucial both the government capacity to attract investments by using fiscal instruments and the high influence, from a Keynesian perspective, that the level of public spending has on the production level and, through this, on unemployment and household consumption. This is perhaps one of the main weaknesses of the European Union construction, as monetary policy is centralized and unique, while fiscal policy is decided at national level. This creates inconsistencies in fiscal policy around the EU and makes correlation with monetary policy virtually impossible, especially in the case in which national governments often choose to ignore the articles of the Maastricht Treaty regarding the restriction of the budget deficit or the ratio between public debt and the gross domestic product. We feel that addressing this issue should represent one of the prevailing objectives of the EU, perhaps taking as a model the more efficient structure of the USA, where even if individual states hold some fiscal autonomy, important fiscal issues are still decided in Washington, thus allowing correlation with the Federal Reserve's monetary policy decisions.

Fiscal policy may also have an impact on closing or widening the gaps between different regions through differences in taxation levels for different economic branches that exhibit relevant geographical concentration and through practices regarding transfer of funds between rich and poor areas. In this way, fiscal actions aimed at uniformization may contribute to a more homogenous monetary policy transmission mechanism (Fatas, 1998: 165).

Before moving forward, it's necessary to focus attention on the way in which expectations regarding future fiscal policy may influence production. For this, we rely on Rankin's (1998) study, which concludes that uncertainty towards future fiscal policy actions may have negative effects on demand in the present, with consequences on prices and productivity. The case of Cyprus, where, while these lines are being written, markets are facing a high level of uncertainty generated by the unknown effects of some controversial bank restructuring actions, is a good (and ongoing) example.

## **6. Conclusion**

The economic climate, and implicitly the monetary policy transmission mechanism, is constantly under pressure from factors that originate from outside the reach of the central bank and often even from outside the control of other national institutions. The external factors have a strong impact on the transmission processes that take place within the monetary policy transmission channels, and thus influence central bank decision-making, as it changes the structure of the cause-effect chain between decisions and economic outcomes. This is a reality which has become more obvious as the processes of globalization and economic and financial integration deepened and is something that the central bank can't fight and from this reason should not even try to. However, this changes the rules of the game that the central bank plays, forcing it to become more alert to potential external shocks and more adaptable to

their effects, so that the decisions it takes successfully navigate through a modified transmission mechanism and alter the economic variables in the intended fashion. The general changes in the global economy, shocks in commodity prices, financial market volatility and national (but non-central bank controlled) fiscal policy are just the main external factors that can modify the transmission mechanism's structure by directly affecting the way in which the transmission channels work. But other exogenous factors may originate in a wide range of external events and the central bank needs to be efficient in clearly identifying the mutations induced in monetary transmission. In an ever more global economy, this ability of the central bank is a crucial condition for the accomplishment of monetary policy objectives.

# THE ASSET PRICE CHANNEL AND ITS ROLE IN MONETARY POLICY TRANSMISSION

**Dan Horațiu**

*Economics and International Business Department, The Faculty of Economics and Business Administration, Babes-Bolyai University, Cluj-Napoca, Romania  
dan.horatiu.sorin@gmail.com*

**Abstract:** *This paper addresses the subject of the monetary policy transmission mechanism by focusing on the asset price channel, which is the monetary transmission channel responsible for the propagation of the effects induced by the monetary policy decisions made by the central bank that affect the price of assets. We will analyze the asset price channel by taking a close look at its structure, internal processes and the way it delivers monetary policy throughout the economy, ultimately influencing key variables such as the unemployment rate and the levels of consumption and production. After an introduction dealing with the entire monetary transmission mechanism, its role and purposes, we will focus on the particularities of the asset price channel and the two main ways in which it delivers monetary policy decision effects: through changes in Tobin's  $q$  value, which is the ratio between the market value of a given company and its replacement cost of capital, and through the effect of wealth, both of financial and housing nature, on consumption. In our study, we will consider theoretical aspects and observations, but also empirical evidence that highlights that the exact way in which the asset price channel functions may differ from one economy to another due to differences in the structures of the respective economies and differences in psychology and cultural values of consumers. The deep understanding of the asset price transmission channel is very important for any central bank, as this is the channel that governs key aspects of monetary policy transmission linked to the market value of assets and individual wealth. These values have, as we will see in more detail throughout the paper, an important impact on both consumption and investment, two economic actions that can help the economy, but can also prove to be a crucial element in starting and perpetuating an economic crisis.*

**Keywords:** monetary transmission; asset price channel.

**JEL classification:** E52; E59.

## 1. Introduction

The monetary policy transmission mechanism is defined in several ways, which we hold as being complementary. Taylor (1995: 11) describes the monetary policy transmission mechanism by assimilating it with the process through which monetary policy decisions are being transmitted, inducing effects on the real gross domestic product (GDP) and inflation, while Ireland (2005: 1) defines it by referring to the fact that "policy-induced changes in the nominal money stock or the short-term nominal interest rate impact real variables such as aggregate output and employment". According to the the Boston Federal Reserve, the monetary policy transmission mechanism is composed of a series of channels that transmit monetary policy decisions through a cause-effect function navigating through the variables of interest

rates, exchange rates, equity prices, real estate prices, bank lending, and firm balance sheets. In this way, the central bank's monetary policy decisions are being distributed in the economy, affecting characteristics like consumption and investment levels, employment and ultimately the price level. The deep understanding of the way in which these channels work is crucial in ensuring the development of efficient and effective monetary policy. This however may prove itself to be a very complex undertaking. Besides the structural changes that come up in the system, and whose nature, magnitude and direction can be exactly known only after at least some of the effects are already in place, there are also some factors that are acting simultaneously and on a constant basis, like external shocks, technical evolution effects and changes in the structure of the economy. These factors continuously alter the relationships that are established between the different elements that make up the economy. This state of fact transforms the study of the monetary policy transmission mechanism in an activity that requires continuous adaptation to new realities within the economic system and a flexible approach on the subject.

Between the different elements of the monetary policy transmission mechanism operate complex interdependencies which create a domino effect, as changes that come up in one compartment reflect in others until they influence the ultimate variable: the price level.

The mechanism is made up of five different channels through which monetary policy decisions are delivered to the economy, affecting its different components with distinct intensities and speeds. The characteristics of each transmission channel are determined by the structural reality that governs each economy, so the exact way in which these channels function differs from one case to another.

The five channels of the monetary policy transmission mechanism are (Loayza, Schmidt-Hebbel, 2002: 4-6):

- the interest rate channel
- the expectations channel
- the asset price channel
- the credit channel
- the exchange rate channel.

From these five channels, the ones that got the most attention from economic literature so far are probably the interest rate channel, the credit channel and the exchange rate channel. However, the importance of the remaining two channels, the ones that deal with expectations of both markets and individual consumers and with the function that asset prices have in transmitting policy decisions, is not to be underestimated. For this reason, the present article will be focused on the study of one of these two channels, i.e. the asset prices channel.

The analysis of the asset price channel leads to the indentication of two key components, or two distinct sub-channels, that regulate the flow of effects from the policy decision toward the final economic variables. The first such sub-channel is functioning based on the principles underlined in Tobin's q Theory (Tobin, 1969), while the second one is dealing with the way in which wealth, more precisely changes in wealth triggered by decisions of the policy makers, influences the economy. Let us address them separately.

## 2. Tobin's q Theory

Tobin's q Theory (Tobin, 1969), named after the economist who developed it, is centered around a variable named q, which is equal to the ratio between the market value of a given company and its replacement cost of capital. A q value greater than 1 signals the fact that the market is taking into consideration a series of assets (usually intangible) which are not reflected in the company's financial statements and is an evidence of the positive perception of the market regarding the company's capacity to generate added value. Similarly, a q value that is smaller than 1 indicates the market's lack of confidence regarding the company's ability to generate added value and, implicitly, a satisfactory financial profit.

A high value of the q variable has a positive impact on investments, as a big market capitalization with respect to the replacement cost of capital indicates that the company is in a position to issue equity at a price that is high in relation with the cost of acquiring new equipment, thus making this an advantageous action, with a direct impact on the general growth of investments within the economy. On the other hand, a small q value shows that the acquisition of companies that have among their assets similar equipments and production factors is a more profitable course of action than buying new ones, so the level of investment is negatively affected (and with it the level of production) due to the increased activity on the mergers and acquisitions market rather than spending for new equipments.

Once the notion of the q variable is clarified, we can proceed to study the place that Tobin's concept has within the monetary policy transmission mechanism. Let us place ourselves in the case in which the money supply falls, which means that interest rates will rise. This will in turn provoke a drop in spending, including the spending level on capital markets, influencing negatively stock prices, as demand falls. In the same time, higher interest rates will alter the profitability ratio between stocks and bonds, putting extra pressure on stock prices. All these effects will lower the value of the q ratio defined by Tobin, which in turn will lead, as we have already seen, to a drop in investments. Similarly, a risen money supply and its consequences on the drop in interest rates will positively affect the evolution of financial assets by facilitating on one hand the capacity of the companies to finance their investment needs from capital markets and on the other hand by making the expansion through the acquisition of other companies more difficult due to their increased market value (Mishkin, 1995: 6). Cumulatively, these factors determine the companies to finance themselves cheaply from the market and used the attracted capital in order to buy new plant and equipment, thus having a positive effect on investment, consumption and, in a desired non-inflationist environment, an important effect on the production level due to the increased demand for those goods. This effect on production is however highly influenced by the elasticity that the supply side exhibits.

Tobin's q values may differ greatly from one country or monetary zone to another. Just to give an example, the mean of Tobin's q for US companies, computed for data gathered between 1994 and 2003, is 5.85 (Ehrmann and Fratzcher, 2004: 20), while in the Euro Zone countries, the value has varied between 1.16 and 1.22 in the 1995-2000 period (Bris, Koskinen and Nilsson, 2003: 8). In Romania, member of the European Union but not of the Euro Zone, Tudor (2011: 14) finds that the mean q value of a sample of companies listed on the Bucharest Stock Exchange is 1.06 (data gathered from 2006 to 2011). Even if periods for data gathering, nor the number and profile of companies, do not fully coincide, big differences are observable, especially between European countries and the US. This highlights the

diverse way of functioning within the asset price channel, leading to extra pressure on central banks to investigate, evaluate and consider the exact state that the asset price channel of their transmission mechanism is in. More, Ehrmann and Fratzcher (2004: 5-6) find that, at least within the US economy, the companies with a high Tobin's q value are affected significantly more by US monetary policy. This finding complicates the central bank's decision making process even further, as it shows that monetary policy actions have heterogeneous effects delivered through the asset price channel.

### **3. The Effect of Wealth on Consumption – General Aspects**

The effect of wealth on consumption is the second theory that we will analyse which falls under the broader concept of the asset price transmission channel. Elaborated by Modigliani (1971) in his life-cycle theory, the effect of the wealth on consumption is monetarist in nature and is based on the concept that the level of consumer spending is determined by the level of the consumer resources. These resources are made up of human capital, real capital and financial wealth. The expansion or contraction of the monetary base, and implicitly the changes in interest rates, alter the values of the available consumer resources, making companies or individuals relatively richer or poorer. According to this, a monetary expansion and its effect of a fall in interest rates will trigger the rise of the real capital component (through the rise in the price of the real estate assets) and of the financial capital (through the rise in prices of stocks and bonds). The mechanism is based on the fact that lower interest rates encourage investments, more precisely the demand for real and financial assets. The resulted rise in wealth will determine their owners to use a part of this growth for either extra investment, either extra consumption, either both. The extra consumption resulted will in its turn generate extra investment because of the adjustment of the supply level, through increased production capacity to the risen demand. It is also worth mentioning that the extra consumption is dependent of the marginal propensity to consume of every particular group which experiences a change in wealth. According to Blanchard (2006: 49), the marginal propensity to consume describes the effect on consumption of an extra monetary unit of disposable income. The scenario in which interest rates rise is to be treated symmetrically and will have opposite effects, in the way of lowering wealth, which will lead to a lower level of consumption and investments.

### **4. The Effect of Wealth on Consumption – An Inter-Regional Analysis**

At the end of the past century and the beginning of the current one, a series of studies were published on the issue of the marginal propensity to consume relative to the aggregate wealth using data from the United States. Out of this series, we focus on those written by Gale and Sabelhaus (1999), Kiley (2000), Davis and Palumbo (2001) which find marginal propensity to consume values between 4 and 7 cents for every dollar of extra wealth.

Other studies, like the one carried out by Mishkin (2007) and Bovin, Kiley and Mishkin (2010), show that there is conclusive evidence that validates the theory according to which wealth changes of same magnitude and in the same socio-economic environment, but in different asset classes, will have a different impact on consumption. We are more precisely talking about changes in real estate housing wealth, which have greater impact on consumption than similar changes in assets that fall under the other asset classes mentioned earlier.

More insight on the topic comes from Catte, Girouard, Price and Andre (2004). In their study of the economies that are members of the Organization for Economic Cooperation and Development (OECD), they found substantial differences in the ways that changes in wealth influence consumption and investments in different countries. According to the study, the propensity to consume generated by both the extra housing wealth and the extra financial wealth differ greatly according to the country we are focusing on and according to the time that has passed from the moment the change in wealth came into play. The values vary from 1 to 8 cents per monetary unit. Of interest are also the very diverse ways in which wealth influences consumption in the studied countries: there are countries in which temporal fluctuations of consumption are big (for example Australia regarding the residential wealth influences and Japan regarding the financial wealth generated changes in consumption), and others in which changes in certain types of wealth influences consumption very modestly, no matter the time frame considered (for example, the residential wealth in France and Germany). On the other hand, other cases show an immediate and high intensity response to such changes in wealth, which is tempered only by the passing of time (like the cases of the United States and Great Britain). However, the paper finds that most economies exhibit a gradual intensification of the propensity to consume with time, followed by a gradual fall once the peak is reached. Table 1 below summarizes the estimated short-term and long-term marginal propensities to consume generated by financial and housing wealth, visible on both short and long-term, in ten OECD countries.

**Table 1:** Short-term and long-term marginal propensities to consume in OECD countries

	Short -term		Long-term	
	Housing	Financial	Housing	Financial
Australia	0,02	..	0,07	0,03
Canada	0,03	0,03	0,06	0,04
France	..	..	..	0,02
Germany	..	0,01	..	0,02
Italy	..	0,01	0,01	0,01
Japan	0,01	..	0,01	0,07
Netherlands	0,02	..	0,08	0,06
Spain	0,01	..	0,02	0,02
United Kingdom	0,08	0,03	0,07	0,04
United States	..	0,02	0,05	0,03

Source: Catte et. all., 2004: 16

Yale University economists Case, Quigley and Shiller (2005) have studied the way in which wealth fluctuations in different asset classes influence consumption levels. Starting from two sets of data, one involving economic data gathered from 14 countries over 25 years (between 1975 and 1999) and the other made out of data

gathered between 1980 and 1990 from the individual states within the USA, the empiric study has reached a series of interesting conclusions, as described below. The first conclusion is that there is at best a weak link between changes in financial stock market related wealth and changes in consumption levels.

The second conclusion reveals a strong correlation between changes in housing wealth and changes in consumption. An explanation for this fact is linked to the rapid development of consumption credit bank products backed with mortgages (same type of products that were at the base of the 2007 economic crisis!). These products make it very easy for home owners to transform the market value of their houses into cash which is immediately available for consumption. The characteristics of the credit market which facilitate the transmission process between housing wealth and consumption are dependent on several variables, like the type of interest (fixed or floating), the costs generated by the credit approval process, the refinancing costs and the flexibility of the mortgage market to changes in demand for housing and thus in housing market value. In the case of the United States and of other highly industrialized countries, which have a banking system which is more developed, highly concurrent and more responsive to market financing needs, there is a higher correlation between fluctuations in housing wealth and consumption, which basically confirms the above detailed observations.

The Case et al study also concludes that, in the case of the international data set, a 10% rise in housing wealth leads, in the analyzed period, to an approximate 1,1% growth in consumption, while a similar rise in the wealth comprising out of stocks has a non-significant impact on the level of consumption. In the case of the American data set, results related to the stock market generated wealth vary substantially, depending to different study models. So, even if the effect of the change in consumption generated by housing wealth remains constant at 0,4% for a 10% change in wealth (with a dynamic of dropping to 0,3% after three semesters and to 0,2% after ten semesters from the initial shock), the values related to the housing wealth generated consumption vary, for the same data set, from 0% to 0,4%. But even if the results generated vary (so they cannot be regarded as error proof from a quantitative perspective) the essence of the findings and the underlying dynamic principles are consistent to other similar studies (even if performed on different data sets), therefore at least the principles and dynamics of the phenomenon, the thing that we most value for the purpose of our study, may be regarded as highly reliable. Sousa (2009) takes a similar perspective on the effects of changes in wealth on consumption in the Euro Zone by using primary trimestrial data from the period between T1 1980 and T4 2007. His conclusions can be summarized as following:

- Changes in financial wealth produce important and statistically significant effects on consumption. Effects are strong especially in connection to wealth changes triggered by the stock market and mutual funds. In figures, a 10% growth of the financial wealth will trigger an immediate 0,6% growth in consumption. This value will eventually peak at 1,5%.
- Effects on consumption that are generated by changes in housing wealth are close to zero and not relevant from a statistic point of view.
- The rise of consumption is persistent and responds slowly to shocks, as the immediate change is of low intensity compared to the longer term one.
- The immediate effect of changes in wealth on consumption is substantially different from the same effect observed over a longer period of time. This fact is indicated by the major negative difference between the immediate

growth in consumption of 0,6% for a 10% growth in financial wealth and that of the longer term growth in consumption which peaks at 1,5% for a 10% growth in financial wealth.

The conclusions of this study are congruent with those of a similar study conducted by Skudelny (2009), which also finds no effect of housing wealth on consumption and important, time persistent and slow effects on consumption triggered by changes in financial wealth. However, the Skudelny study evaluates the marginal propensity to consume as being more modest, i.e. a 10% raise in wealth will generate a 0,13% growth in immediate consumption and a 0,35% growth on the long run.

We see rather significant differences between studies. However, these differences are based in a small extent on the interpretation methodology of the raw data, but more on differences in data sets from both a geographical/economic area and time point of view. The most important differences can be found when comparing results from the United States and the Euro Zone, differences which are linked less to the exact values of the marginal propensity to consume, but on the fundamentally different way in which these economic areas function, a fact that is underlined by the big differences in which the two main subcomponents of wealth (financial and housing) influence consumption (or fail to do so). We can include these differences into two categories:

The first category includes differences regarding the sub-component of wealth that influences consumption. More precisely, if in the United States the only sub-component with effects on consumption is the housing wealth while the financial wealth has no statistically significant effects, in the case of the Euro Zone things are exactly the opposite. Here, the financial wealth has the potential to influence consumption, while, for Europeans, the values from housing market do not represent a consumption altering factor. An explanation for this lies in the following:

- There are significant differences in the functioning of the banking system and consumer credit behavior between the two regions. In the USA, the mortgage based credit is highly developed and widespread, being a direct and easy way to transform housing market value into consumption capital. In contrast, in the Euro Zone this type of credit product is less spread, so changes in housing value don't have such a strong transmission channel and thus don't have an impact, at least not a significant one, on the consumption level.
- The public view on the two components of the financial wealth that may have an impact on consumption, i.e. stocks and mutual fund participation, is fundamentally different, as in the United States these instruments are being regarded from a more long-term investment perspective than in Europe, being the base of a greater number and variety of long-term saving vehicles, like pension funds or college funds.

The second category is made out of differences regarding the persistence of consumption and the time needed for it to react at shocks in wealth. In the USA, where consumption is influenced by housing wealth, we can observe a fast reaction to wealth changes, after which the advance in consumption is prone to drop in an almost linear fashion, provided that no new shock comes into play. According to Case et al. (2005), this drops with a quarter after four semesters and by half after ten semesters have gone by from the initial shock in housing wealth. In the Euro Zone however, things look just the opposite, as consumption has a higher initial resistance to changes in financial wealth (which, as seen, is the only one affecting

consumption in the Euro Zone), just to experience a sustained ascending trend later on, even in the absence of a new shock in wealth levels.

These studies and their findings, are different depending on the economies taken into consideration. They confirm the strong link between wealth effects and the consumption sub-channels (and consequently of the entire asset price channel) on one hand, and behavioral sciences on the other, as consumer mentality plays a decisive role in the way the relationship between wealth and macroeconomic context is carried out. These effects on consumption and, implicitly, on investments are not linear or uniform, but highly dependent of a series of social, economic and cultural factors, characteristic for each geographical area or population. The sensitivity exhibited by consumption spending relative to changes in wealth depends on a wide series of factors linked to the functioning of credit markets and the habits of consumers. Of great importance are the elements which reflect the tendencies to finance consumption, the size and composition of wealth and the perception of the persistence of change in the prices of relevant assets.

## **5. Conclusion**

The theories surrounding the asset price channel come as additional to the classic views on the monetary policy transmission mechanism, which are based on money supply effects that navigate through the interest rate channel, the credit channel and the exchange rate channel. These theories are complementary to the more traditional ones dealing with the above mentioned channels, as they cover key areas in understanding the complex phenomena that take place within the economy as a consequence of monetary policy decisions. As we have seen, asset prices directly affect wealth, both of households and companies, with a great impact on investment and consumption. From a company point of view, theories based on Tobin's  $q$  value clearly show that asset prices are decisive in the decision between greenfield investments, with consequences on production levels, on one hand, and mergers and acquisitions, which imply that no new plant or equipment is bought from producers, on the other. From a household perspective, the wealth level, made out of the housing wealth level and the financial wealth level, influences consumption based on a mixture of economical, psychological and cultural criteria that is unique for every community, thus bringing differences in asset price channel functioning between economies and even heterogeneity in certain monetary zones. So, even if less reflected by the economic literature dealing with monetary policy transmission mechanisms than the so called traditional channels, the asset price channel is of great importance and, as proven in the previous years, its elements may also have significant consequences on the economy. These consequences can be both positive, by providing efficient means of transmitting monetary policy decisions, and negative, by allowing debt and consumption to reach unsustainable levels. This is the case of the profile discussed earlier, that has played a major part in the 2007 economic crisis, as the intense functioning of the housing channel linked the bubble from the housing market with the banking system, while at the same time the extra consumption that was generated by this link was fueling bubbles all across the economy. In this context, central banks need to profoundly understand the processes that take place within the asset price channel. This has to be done keeping in mind that, besides the general functioning principles of the channel, some points of potential inter-regional heterogeneity may appear. These points of difference may, as we have seen, manifest themselves with regard to the impact of

financial and housing wealth on consumption. The complex structure of the asset price transmission channel is yet another argument for central bank attention, as its efficient and effective use is crucial for the accomplishment of macroeconomic objectives.

**Abstract:** *The project "Practical training of economist's students. Inter-regional partnership in the labor market between universities and the business environment" focuses on student's transition from school to labor market. Concretely, it tries to highlight the general role of practical training – specifically the field related practical training set as a mandatory discipline in the curriculum, by identifying possibilities of interventions from supervisors. Starting with literature review regarding determinants of school to active life transition, the present contribution discusses the outline of the practical training set as a mandatory discipline in the curriculum. Within PRACTeam project the practical training itself is accompanied with a series of supplementary services (aptitude testing, counseling, career guidance, mentoring by a trained tutor, granting financial aid, awarding excellence over contests and internships). It represents an active partnership on the labor market meant to address directly students' expectations regarding practical training, work, and entrepreneurship. At least two main benefits may be derived from the training and tutoring. First, as a dual type model of transition from school to active life, allowing students to become insiders in the labor market. Secondly, changes in supervisor' patterns of interactions and behavior/attitudes toward work and employees may also occur, which in turn may improve the work. A pretest-posttest non-experimental design was applied for the PRACTeam evaluation. Using administered questionnaires and focus group method to students before and after they completed their practical stages we examined their attitudes and behavior towards elements of the dual model of transition. The paper concludes that a dual type model of transition from school to active life - that implies the education and practice occur simultaneously, successfully meets students' expectancies and may be functional for improving permeability between professional and academic knowledge.*

## 1. Introduction

Dramatically rising of youth unemployment and tougher conditions faced by youth in entering the labor market are major social and economic challenges of this decade across Europe (OECD, 2012). There are approximately five million unemployed youth (those under the age of 25) in the European Union (EU). The youth unemployment rate in the EU was 22.3% in November 2011 - more than double than unemployment rate - 9.8% (Eurostat, 2012; OECD Statistics, 2012). The highest youth unemployment rates (around 30%) were registered in the most affected by economic crisis EU Member States: Greece, Italy, Latvia, Lithuania, Portugal, Slovakia, Spain and Ireland (OECD, 2012) but, as OECD shows, the increase in youth unemployment was not much more than for adults in the context of recession (OECD, 2012). The problem of youth unemployment is chronic across Europe. Moreover, labor market integration of graduates is severely threatened by requesting work experience from employers. In this context, the general concern is for search "approaches that work" in helping young people to enter the labor market for their first job. Investigating the factors that can facilitate transition from school to active life or keys for success for youth insertion on labor market are research areas that intensified in recent years across the EU.

## 2. Theoretical model of determinants of school to active life transition

Practical training and work experience within different educational forms, are considered key factors in facilitating the transition from school to active life and labor insertion of graduates (Cardosa, 2004; Hill and Holzer, 2006; Tovatt, 2011; Bell and Blanckflower, 2011). Transition from school to active life is defined as the process of change from the life of a youngster included in an educational form to the independent life. Current approaches distinguish between *transitions from school to active life* from the *labor market insertion* as the first does not assume the completion of studies. It may take place within an educational process under the form of practical training (Garcia, 2007, apud. Pîrciog et al., 2010: p. 75). The latter reflects employment after graduation of studies (Hill and Holzer, 2006).

Nevertheless this distinction is sometimes unclear as the succession school-work does not necessarily follow the classical model: employment may alternate with periods of inactivity, periods of schooling and work may overlap or even be reversed. More, school-to-work transition is differentiated between countries based on the link between educational systems and labor market, the standardization of educational outcomes at national level, openness to choice through the educational path. This is largely known as the *dual model* in which education and practical training take place simultaneously, allowing the student to become an "insider" on the labor market during his or her studies. The educational system is more standardized and stratified having close links with business organizations; links that develop continuous offers of internship or jobs for graduates etc. This is the success model for the youth insertion on the labor market (Mickovska-Raleva, 2010; Van Der Velden and Wolbers, 2003; Ehlert and Cordier, 2002). Another "way-out" from the classical model is given by the *entrepreneurial experiences* and *self-employment* as professional integration and, as processes of transition from school to active life and/or insertion on the labor market. Consequently, this current model moves away from the classical one (continuous, linear and homogenous), as it is rather discontinuous, un-linear and un-homogenous.

In the search of a theoretical model of determinants of school to active life, the founding theories are: the *human capital theory* (Becker, 1964), *job-competition model* (Thurow, 1975), *the job search theory* (McCall, 1970; Mortensen, 1970) and the *insider-outsider theory* (Linbeck and Snower, 1988).

Becker's *human capital theory* is the first approach in the economical thought regarding the behavior towards education and the implications of education on the labor market reflected over the salary differences between different educational levels (Becker, G., 1964). The author considers that "education and professional training are the most important investments in human capital" (p. 45). Nevertheless employers are not interested merely in the value of a diploma but also on the acquisition of "capacities and performances on the context of productive work". McCall's (1970) and Mortensen's (1970) *job search theory* as well as Thurow's (1975) *job-competition model* open the "Pandora's box" in the search of determinants of work insertion. The first determinant is the salary as job search behavior reveals it is an important criterion in accepting or rejecting a job (McCall, 1970; Mortensen, 1970). Next, analyses highlight the defensive importance of education and the level of compatibility of qualifications needed on the labor market and those provided by the educational system (Thurow, 1975).

These aspects are particularly relevant for youth as they are the most vulnerable to become unemployed. They are the end of the waiting line when jobs are scarce as employing new-comers increases the training costs for the company (Thurow, 1975). The *insider-outsider theory*, makes the distinction between employees and unemployed, and reveals that most youth graduating any form of education are outsiders competing with insiders with more experience (Linbeck & Snower, 1988). Other studies analyze the quality of jobs acquired by youth or the impact of different factors on unemployment among youth. For example macro-economic conditions, dimension of youth cohort, educational level, occupational structure, institutional arrangements shaping opportunities for new-comers on the labor market, occupational and educational policies (van der Velden & Wolbers, 2003).

We consider relevant for analyzing the determinants of school to active life transition also some recent studies. Reimer, Noelke, et al. (2008) explain cross-national patterns of labor market entry among students who drop out in 11 European countries. Reimer, Noelke & Alexander's (2008) analyzed the impact on occupational status of university graduates using data from 22 countries showing that differences in labor market opportunities for university graduates from different fields of study increase with the expansion of education at university level. Smyth & Banks (2012) identified the following key influences that shape the choices of young people: individual habitus, institutional habitus of the school (amount and type of guidance provided), personal agenda of each young, and how they evaluate alternatives. Authors explore how patterns of institutional differentiation in higher education systems are related to educational inequalities at the time of transition from higher education to work.

Starting with these, our analysis will try to highlight the general role of practical training – specifically the field related practical training set as a mandatory discipline in the curriculum. More, in this case, the practical training is conducted within a project that accompanies the practical training itself with a series of supplementary services (aptitude testing, counseling, career guidance, mentoring by a trained tutor, granting financial aid to all participants, stimulating education and professional integration by awarding excellence over contests, and internships etc). All these are

accomplished through an active partnership on the labor market for facilitating the *transition from school to active life* of economics' students from Bihor, Timisoara and Suceava counties (Romania) and responding to the students' expectations regarding practical training, work, and entrepreneurship.

### **3. Methodological design**

Our endeavor is based on the experience of PRACTeam project: "Practical training of economist's students. Inter-regional partnership in the labor market between universities and the business environment", financed through European Social Fund - "Investing in People!" Contract no. POSDRU/90/2.1/S/64150. Within the project special emphasis was put on cooperation and collaboration between all actors involved in the practical training of students: students, teachers and representatives of the labor market. Consequently determining student's expectations regarding both the practical training and work (employed or self-employed) were the two aims of several research activities.

In order to *identify students' expectations regarding practical training* we have developed a methodology describing both the instruments and the sample for each of the three years in which the methodology was implemented. In the first year we administered questionnaires to students which completed their practical training in all three Faculties as well as focus groups with candidates. The second wave of assessment was based on focus groups with three type of groups: PRACTeam graduates (students from both BA and MA level which have completed their practical training within the project), non-PRACTeam graduates (students from both BA and MA level which have completed their practical training outside the project), and candidates. In the last year we have conducted focus groups solely with candidates from both BA and MA level. There were 30 focus groups organized, with an average of 12 students from different educational programs.

More, in the second year the managerial team of the project initiated a research on the broad topic *Students' Transition from school to work*. The survey was based on an on-line questionnaire composing in several topics from assessment of competences and interests related to work, psychological attitudes and values to aspects regarding social capital of students. The data collection is still on-going thus the results presented in this paper is based on a preliminary data base consisting of 374 valid responses obtained from students from all partners in the project.

The analysis presented in this article is based on both these sources of data: the identification of expectancies regarding practical training and the survey.

### **4. Main findings and discussion**

#### **4.1. Students' expectations regarding practical training**

The focus groups aimed at assessing the impact of the practical training. The results were grouped in the following dimensions that were considered relevant: best practices in terms of the practical training of students, the strengths and threats on the organization of practical training, and other problems in the development stages of the training program.

Most students reported positive experiences. When problems were mentioned students reported those problems were faced by "other fellow" detaching themselves from them. In this section we mention some examples that can be considered best practice models. As highlighted during the discussions, these detailed models could

be positive in terms of the companies as responsible business practice and as work attitudes of students in practice.

One of the first aspects that were appreciated by students represent the firm / company / institution. The interest, attention and time spent by tutors with their students were the cases where students were most satisfied. The best practices are considered the situations where students had the opportunity to visit different departments or offices interacting with more people from each company.

*"we were involved in a multitude of activities, seen various accounting documents, managed documents and recorded all data in the program. From a practical standpoint, we made all kinds of trainings in effective production hall, [...]. Within 2 weeks of practice I can say that I made a lot of activities, from accounting stuff, script to actually work in practice."* (Andrew, PRACTeam graduate).

In the same manner were assessed the instances where the student has actually worked with several employees of the firm learning from many people:

*"I didn't work entirely with my tutor, but I have met other people ... and for questions and problems we could turn to tutor, but it was better, they actually took the time to show us everything."* (Adriana, PRACTeam graduate)

Indirectly determined as a model of good practice where the situations where students were allowed to make real actions. Often they noted with regret that just watched how to do business (accounting data entry, inventory paperwork and process, performance of contracts, receiving guests at the hotel, credit dossiers and so on) without being allowed to actually contribute to the processes.

During discussions with graduate students no special references were made regarding how the university tutors fulfilled their duties. We believe that this is because no problems were encountered so no issue was mentioned in terms of their involvement. Tutors which constantly monitored the activity of their students were appreciated by their students.

During focus groups it was emphasized the importance of students' attitudes regarding practical training. Several models have emerged from these discussions are detailed in the next section.

This type of problem has occurred mainly in the discussion with students that conducted their practical training outside the project, working students, mostly realizing practical work at their job. However, personal experiences of these students have shown the importance of involving people, perseverance and insistence on tutoring. Three of the participants in this group obtained their job after a successful completion of practical training as undergraduate students:

*"I've been practicing my license at ---, heritage department. After the first day they sent me home but I called and told that I had a number of hours to do practice...and only because I insisted they let me work."* (Mirela, non-PRACTeam graduate)

In this sense, students must be active in education generally, and particularly in connection with practical work experience. Thus volunteering in an organization is viewed as a model of good practice among students as it provides the required job experience.

*"Students miss huge opportunity because they are not involved. At least 2 hours to be ready to learn each day. Have time for their future, not only for coffee. You have to change something in order to be good."* (Lavinia, non-PRACTeam graduate)

*"For example at my working place, last year came a MA student from Moldova. She came as a volunteer, not paid the first two months, to learn the human resources. Now she is hired ... additionally was rewarded for the two months of volunteer work."* (Laura, non-PRACTeam graduate)

Problems arising from student attitudes can be directly addressed by explanations provided by the practice managers and tutors regarding the importance and effect of the actions that they make.

One of the major risks, reported directly by one of the graduate students was related to departments in which they do practice activity - they have to be adequate to the student domain of knowledge.

Another important issue is related to practice time, especially for firms and accounting departments.

*"Yes for those in accounting, July is not the best time of the year, the end of the quarter, it's crazy ... and April and normally that firms do not have the time, and we stand after hours ... no time and explain to others how thing works in the firm."*(Mirela, a non-PRACTeam graduate student).

In the discussion of non-PRACTeam graduates they drew attention to a potential risk in terms of practical training: due to the short duration and the fact that it is often only the presentation of the company / firm and some related action, the image created is " beautiful ", and fails to capture the complexity of the type of problems handled every day.

*"Yes I've heard, some colleagues were to one firm--- but they showed only that everything goes well ... no company showed them problems."*(Monica, non-PRACTeam graduate)

Consequently we believe that learning by doing is an important approach for the practical training. It is important to note also that practical training should also go beyond the required curricula and students should get involved, voluntarily or part time in different organizations.

#### 4.2. Students' expectations and attitudes regarding work – draft 1

The attitudes regarding work were analyzed through the on-line survey conducted with students, PRACTeam graduates, from all three Universities. In this section we present the analysis of some of the questions revealing the importance attributed to work and dimensions valued in work by students.

Regarding the first aspect, it is interesting to note that students have the same responses as generally Romanians. In a percentage of 54% students consider work as a very important aspect of life, below family which is highly valued by 91% of students. At national level in average 56% Romanians consider work as important, while family is important for 86% (Comsa, 2009). A comparison between students' responses and the national findings reveal that the hierarchy of areas of life is the same for the two groups, yet the percentages differ. Table no. 1 describes the answers of students.

Table no. 1. Importance of different areas of life

Areas of life	Very important	important	Less important	Nat at all important
Family	<b>91,40%</b>	8,00%	0,00%	0,50%
Work	<b>54,30%</b>	44,10%	1,10%	0,50%
Religion	31,30%	41,70%	19,50%	7,50%
Friends and acquaintances	22,50%	67,60%	9,40%	0,50%
Free time	19,00%	67,60%	11,80%	1,60%
Politics	1,10%	9,40%	48,90%	40,60%

Regarding the second dimensions analyzed, students consider that it is most important that jobs are fit to their capacities – 70%, that it allows learning new skills – 70%, and that it promotes achieving something – 67%, as shown in Table 2. At national level, the most important feature of a job (95% of respondents considering it very important) referred to “good pay”, followed by security (85%), people treated equally and working with pleasant people (both last dimensions with 79%).

*Table no. 2. Importance of different job characteristics*

<i>Which of the following aspects do you consider important regarding a job?</i>	Very important	Important	Little important	Not at all important
	%	%	%	%
Meeting abilities	71,66	26,20	2,14	0,00
Learning new skills	70,32	25,40	4,28	0,00
Achieving something	67,38	31,02	1,34	0,27
Job security	63,90	32,35	3,48	0,27
Pleasant people	60,43	36,63	2,94	0,00
People treated equally	59,89	33,42	5,08	1,60
Family friendly	54,81	32,09	11,23	1,87
Interesting job	51,07	45,72	3,21	0,00
Good pay	39,04	58,56	2,41	0,00
Use initiative	32,62	57,75	9,63	0,00
Have a say	25,40	62,03	12,03	0,53
Good hours	25,13	60,43	14,17	0,27
Responsible job	24,87	62,57	12,03	0,53
Meeting people	19,79	55,35	21,93	2,94
Useful for society	17,91	47,59	29,95	4,55
Generous holidays	9,09	39,57	46,52	4,81
Not too much pressure	5,08	33,42	54,01	7,49

The way people see work gives significant insight regarding a given society. Students’ responses show a tendency towards valorization of work. Work is viewed mostly as a place where one can express their skills, people who do not work become lazy, its humiliating to receive money without work, work is a duty towards society, and work must come first even if it means less free time.

*Table no. 3. Attitudes towards work*

<i>Do you agree with the following statement?</i>	agree	Not agree nor disagree	disagree
One must have a job to express one’s skills.	<b>81.02</b>	16.31	2.67
People who do not work become lazy	<b>67.92</b>	23.26	8.82
Its humiliating to receive money without work	<b>48.94</b>	38.77	12.29
Work is a duty towards society	<b>40.37</b>	42.51	17.11
Work must come first even if it means less free time.	<b>37.43</b>	37.43	25.13

### 4.3. Students' and entrepreneurship

Since 1989 Romania has experienced significant changes in social and economic. Given the lack of entrepreneurial tradition, youngster's decision to set up a new business is determined in parallel by a number of contextual factors. Academic environment can and should take into account important social impact it can have to support entrepreneurship among young students. "Given that entrepreneurship is one of the most important guidelines towards economic health and prosperity perspective, the development of a true middle strata of society, the theme of entrepreneurship in young people is of particular importance to social responsibility of universities and educational system generally beyond the economic implications and mentality that attracts" (Boarescu, 2011).

Entrepreneurial approach has specific characteristics of young students resulting from a number of factors such as educational level, family entrepreneurship tradition, and charge level with responsibilities. Duties arising from the quality of student and the multiple roles assumed daily make entrepreneurship task more difficult than in the case of young people without academic commitments. Economic environment during the crisis is competitive and does not provide any exemption. Against this background there are many failures, which can be a major risk factor and a demotivating factor in the medium or long term. These aspects should be taken into account by any research aimed at student entrepreneurs. In academia is, more than ever, a need to stimulate the appetite for entrepreneurship and find suitable methods to support legally additional facilities for youth.

Existence of positive models of entrepreneurial activity is, as shown in our research (PRACTeam project) an important determinant of personal choice to engage in entrepreneurial activities.

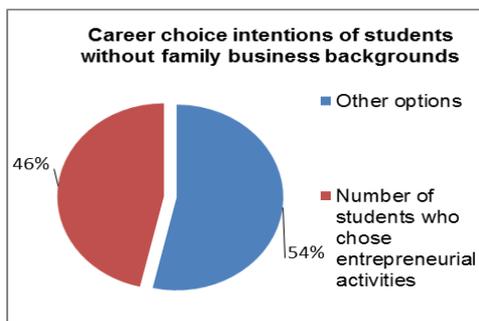

Figure no. 1. Career choice of students without family business backgrounds

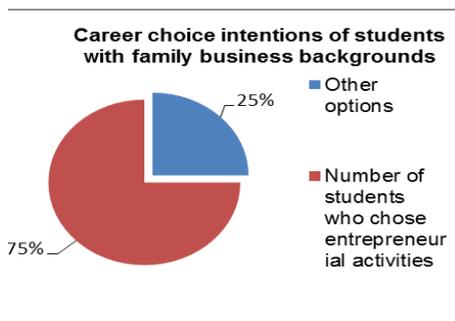

Figure no. 2. Career choice of students with family business backgrounds

From statistical perspective it can be seen that the percentage of students who are determined to engage in a business and from families engaged in various entrepreneurial activities or links with business is one third higher than the percentage of students who want to do business without have a tradition of entrepreneurship in family of origin. The existence of a mentoring model appears as a significant factor for the availability to start a business. In this context it is clear that the University should play a role not only in the theoretical training of students, but

should enable them to enter as often in contact with successful entrepreneurial models.

## 5. Concluding remarks and future perspectives

Synthetically we can say that our analysis shows that PRACTeam model – as a *dual type model of transition from school to active life* - that implies the education and practice occur simultaneously, allowing students to become insiders in the labor market even during studies and education has very close links with business organizations, successfully meet students' expectancies. At least two main benefits may be derived from our model of practical training. First, it allows students to become insiders in the labor market. Secondly, changes in supervisor' patterns of interactions and behavior towards work and employees may also occur, improving the quality of work. The broad scope of education and practice may be functional in reducing unemployment rate as well as for improving permeability between professional and academic knowledge.

We will continue to monitor *graduates, practice tutors and managers of host organizations expectancies* in order to identify the needs for practice stages for students in Economic Sciences of the Bihor, Timis and Suceava counties and to evaluate de impact of PRACTeam model labour market partnership (survey of the structured questionnaire applied to graduates which has benefited practice and internship stages through PRACTeam project, survey of the structured questionnaire applied to PRACTeam practice tutors, and open structured interview applied to managers of PRACTeam practice host organizations).

# **SPECIFIC APPROACHES OF PRODUCTIVITY IN SERVICES. VALUES OF SEVERAL COMPARATIVE INDICATORS**

**Jivan Alexandru, Toth Maria**

*Department of Economics and Mathematical Modelling, Faculty of Economics and Business Administration, West University, Timisoara, Romania*

[alexandrujivan@gmail.com](mailto:alexandrujivan@gmail.com)

[toth.maria86@gmail.com](mailto:toth.maria86@gmail.com)

**Abstract:** *The paper proposes a synthesis of several specific approaches of productivity in services, in order to provide a better argued theoretical basis for a realistic assessment of the values of several comparative indicators. From a conceptual point of view, the paper will take as a base some definitions of productivity as a quantitative and industrial indicator, revealing certain aspects that need a widening of the area of approach, in the purpose of being suitable for immaterial activities. Based on the brief analysis of productivity, performance and servicity indicators, the research establishes correlations between them in the immaterial field. Elder and, as well, most recent analyses found in the field literature are used, from most rigorous sources, and they are supplemented with own approaches; such approaches ore pointing out several most specific features that are specially set for services and intellect-intensive activities. Technical and financial aspects of common productivity are taken into account, as well as performance in realising various goals, non-economic here included, and the service components, in a complex approach. The presentation focus on nuance features in the quoted references, in the purpose of a fine defining of the indictors and approaches. Specific particularization is achieved based on the literature. Methodologically, the paper is approaching in an unorthodox manner, the plus of value issued from the human activity, i.e. being in a view coming from a fine analysis of the service performed by any economic activity, in a market system. The conceptual importance of these comparative indicators is concisely highlighted, and it consists mainly in the opening that can become a useful ground for practical applicative analyses, which actually are proposed in the future developments of the topic. The research results reveal the relationship between these comparative indicators as well as some conceptual differences between them. Their application can be made for material and immaterial economic activities, at different levels of economic entities concerned.*

## **1. Introduction**

The economic growth practiced and preached in the modern world (especially in the consumer society) is, in essence, that conceived since the dawn of industrialization and carried out since then (and even today), in forms focused on quantity, counting always on the growth of productivity, regardless of the physical or pecuniary forms

to express this indicator, which became the central (and defining) principle of the desired (targeted) and achieved developments in the economy.

The implications of these approaches are profound and we also find them in the new big crisis. They arise, in essence, from the quantitative concept of productivity in terms of market mechanisms (directed by the development of short and medium term interests in the specific individualistic approach).

Although the formula of productivity is very well-known, as the ratio of the output quantity studied and factors necessary to achieve that output (Fourastié, 1952: 53), one cannot in any way say that this indicator does not bear (anymore) discussions (even controversies, especially when it comes to services). And the most justified debate fosters the qualitative (or quality-related) aspects and the possibilities of "quantifying" the qualitative aspect.

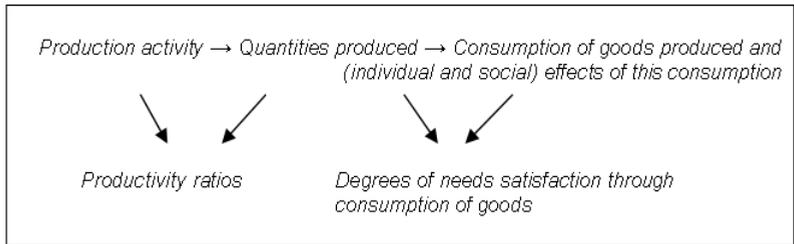

## **2. Productivity, Performance, Servicity**

Vincent André (1968: 1), like most economists, advanced the phrase of productivity from an industrial point of view, but also noticed the presence of quality. Vincent mentions the existence of causal relationships that suggest the idea of social productivity; the author considers this latter type of relationships very complex and difficult to measure because of the intervention of numerous psychological and sociological factors representing the qualitative aspect of the issue. (Vincent, 1968: 1) Hence the difference between productivity calculated and recorded in the national accounts and real (causally defined) productivity. In both Manoilescu (1986: 67) and Vincent's ideatics, we note the tendency of mentioning also the quality aspects that are difficult to quantify, which is relevant to the insufficient and inadequate nature for the analysis of the immaterial, of the concept of productivity, as understood at present.

We recall the importance of "harmony" and "co-operation" that, for example, List and Manoilescu mentioned, to make best use of the system's synergy by combining various factors, with so different results in various systems (individual and national economic entities). At the multitude of effects and correlations that can be established in the tertiary sector, Jacques De Bandt's developments should also be added. He considers productivity an absolutely central concept, the result of economic activity (De Bandt, 1991: 115). The French economist says that "the most used and accepted measure of productivity is the one that measures the evolution of the value added in volume compared to the evolution of each of the factors considered separately (partial or apparent productivity) or to the weighted evolution of all factors (in quantity or volume)" (De Bandt, 1991: 116) and "it is quite difficult to accept the number of services (number of advice, number of medical consultations, ...) as indicators of quantity" (De Bandt, 1991: 118), because each service provided, each medical consultation, for example, is a single service, each medical case has a particular feature and manifests differently from person to person, even every doctor has a certain (moral or professional) behaviour according to the particularity of each case.

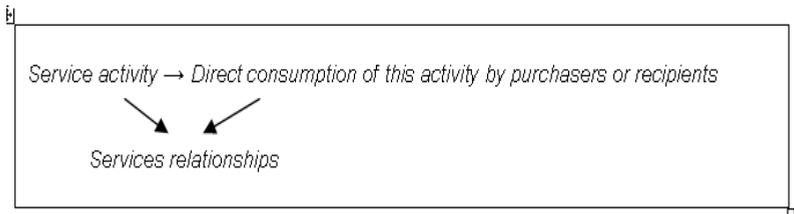

Jean Gadrey points out (as most economists who have studied the tertiary sector) that the notion of productivity is related to the material output (Gadrey, 1996: 54), and certainly not to the immaterial output. In this regard, two schemes proposed by Gadrey raised particular attention (that we name by type of activity - material or immaterial – that each of them refers to, as shown below). (Gadrey, 1996: 54) They

show that the notion of productivity, as defined and formulated in the material sector, is not found in the theory of services.

**Figure 1:** Analysis of productivity in material output

Source: Gadrey, Jean, *Services: la productivité en question*, Paris: Desclée de Brouwer, 1996, p. 54

**Figure 2:** Analysis of the so-called productivity in immaterial activities

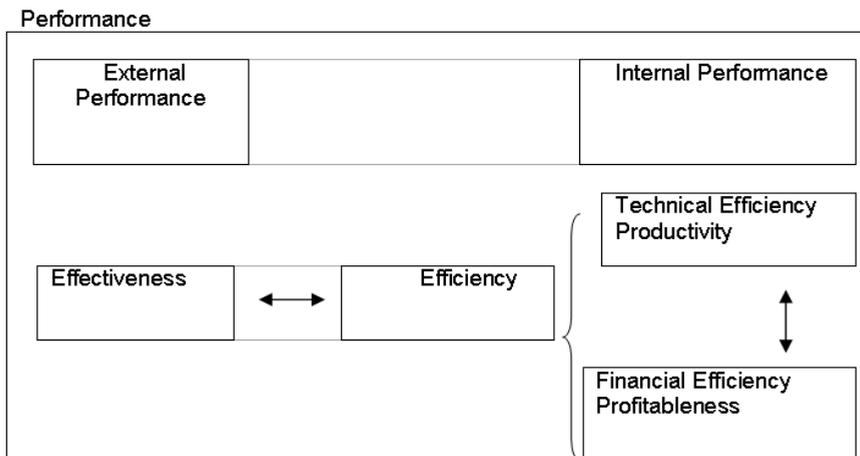

Source: Gadrey, Jean, *Services: la productivité en question*, Paris: Desclée de Brouwer, 1996, p. 55

As can be seen in Figure 1, between production activity and quantities produced there are different productivity ratios expressed quantitatively and not qualitatively, and between the latter and consumption of goods produced there are different degrees of needs satisfaction only through consumption of goods, according to the utility of each good produced for a consumer at a given time. Productivity, as an indicator of technical efficiency, measures a technical performance, i.e. "a ratio of output volume and input volume". (Djellal and Gallouj, 2006: 12) In contrast, in service activity, it is consumed even at the time it is produced (see Figure 2) "the product" of the service cannot be stored and consumed later, the needs of service consumers are highly satisfied, otherwise they will not choose the same provider in the future. We keep this observation for analysis (1)

By analogy with material output relationships (productivity ratios), we added to the figure 2 of Gadrey "service relationships" being characteristic to relationships that are established between people in the event of such services, in this case, between the provider and the customer. Such relationships relate to the quality of services and are intended to offer providers faithful (or not) customers and thus to consolidate (or not) market position. These service relationships include of course the satisfaction level of consumers who use those services. The result is a wider coverage of the servicity over performance. In terms of productivity, this particular service relationship other than the relationship that relies solely on productivity growth is likely to emphasize the special nature of productivity in services itself and

therefore the impossibility to use the usual (industrial) productivity indicators for services, particularly for pure services or with high immateriality.

Gadrey considers the notion of productivity only a partial criterion of the efficiency, idea pursued by the economists Djellal and Gallouj - see figure 3 - ("direct", "immediate" or "intermediate"), and in the case of services, the economic and sociological analysis is focused mainly on the "indirect", "mediated" or "end-type" effects on users, depending on the specific existing social relationship and the time horizon of their impact (Gadrey, 1996: 57). In this respect, Gadrey (1988: 67) distinguishes between *direct* and *immediate output* (nature and quantity of services consumed; notion that is relevant for market services and defines the services paid for the commodity unit transacted) and *indirect* or *mediated output* (service effects on their beneficiaries). The latter concept is actually the *outcome* (long term outcome) in services and depends on the quality of participants or social structures that form around their actions (Gadrey, 1988: 67).

**Figure 3:** Productivity, efficiency, effectiveness, performance  
 Source: Djellal, F. and Gallouj, F. (2012: 26)

For Djellal and Gallouj (2012: 24), the concept of performance incorporates the concepts of efficiency and effectiveness: they define the concepts as follows (Jivan, 2013): performance is the ability of an organization to achieve a variety of objectives (economic, social, political, ethical etc.), a priori fixed and containing various aspects related to the development of that organization. This concept can be seen in terms of internal performance (efficiency) and external performance (effectiveness).

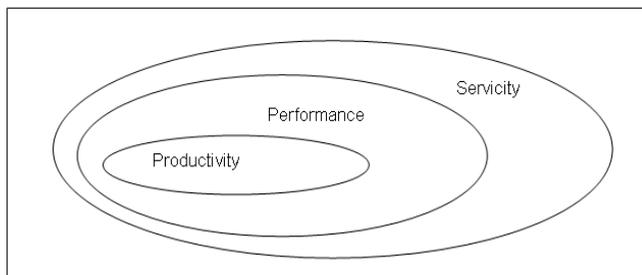

Effectiveness is the measure for achieving goals (regardless of their nature: economic, social, political etc.). External performance is related to the notion of *mediated* or *indirect output* or to the *outcome*, i.e. external performance also includes other types of effects, for both the provider and the user. Efficiency measures objectives (often economic objectives) that have been achieved by saving resources. As can be seen in Figure 3, there are two types of efficiency: technical efficiency (productivity expressed as the ratio of *output* volume and *input* volume) and financial efficiency (expressed through the rate of profitableness).

In respect of these delimitations, one must observe (Jivan, 2013) that in addition to the efficiency regarding the organization's objectives, the efficiency beyond the

concerns (interests) of the economic entity analyzed was not taken into account, which is a kind of "external efficiency" compared to the efficiency evidenced by Djellal & Gallouj, in the sense that it is seen (designed and perceived) in terms of the environmental framework of that organization (natural, social environment etc.). Hence, it also considers (takes into account) the profound effects on others, not just on the economic agent under study. This is a second observation to submit for analysis (2)

In this type of approach, thus extended (according to the servicity's perspective Jivan, 2000), the performance indicator appears as a quantitative indicator, like the others, (successfully used in the industry), rather than a mostly qualitative indicator. In contrast, the servicity concept includes (is larger than) the concept of performance defined above (i.e. how it is understood in the industry), along with the efficiency and effectiveness components (as defined by the economists Djellal and Gallouj). To understand these concepts and nuances that make the difference between them (for the definition of terms), the distinction between internal performance and external performance (*targeted* by the entity under analysis - highlighted by Djellal&Gallouj) is essential, along with their differentiation, in addition (highlighted by Jivan - made by the criterion of servicity) to the external performance not covered by the sphere of interest of the entity under discussion (is *ignored* or, at least, was not considered a main objective).

The two observations we made (1) and (2) lead to the conclusion of our research focus of bringing in actuality a concept that appears as the result of a synergistic approach, taking into account the effects for both the provider and the consumer, *i.e.* servicity (Jivan, 2000), a concept encompassing the complex efficiency issue (economic, social, environmental, political, moral, spiritual and human etc.) of human activities, by establishing numerous correlations between providers and beneficiaries – see the insert made to the figure 2), as well as between providers or beneficiaries and the external environment (see figure 4).

**Figure 4:** Productivity, performance, servicity

Source: Outline by descriptions on the topic from Jivan (2013)

Servicity, in the narrow sense (Jivan, 2000: 94), expresses the productivity outside the entity analyzed and "expresses *aspects of the utility other than profit*, it means performance, effectiveness, externalities and other implications than those covered by the entity under analysis." Broadly, servicity means "*the utility made available to the beneficiary of the activity (service)*, when the agent that provides the service is not regarded as a *totum factum* (from an individualistic perspective), but integrated into an existing utility frame from which he also benefits.

So, servicity is expressed by *utility over these conditions*, that is the utility created by the economic agent over the utility enjoyed by himself for his activity, or his contribution over the conditions that allowed his contribution, or the way he knew how to receive (and capitalize on) what he has received or how to create over what has been created (from a practical perspective of the activity under consideration), or how he was able to give something (through that activity), while he has received something (for the activity).” (Jivan, 2000: 102) For example, physicians have received medical-themed lessons through the educational system to be able afterwards to exploit, through their own contribution, these lessons in treating various diseases (depending on the specialization assumed): the contribution of doctors requires their efforts and dedication, including an associated opportunity cost. And the healed patients in turn will re-involve in the economic life, creating new values and benefiting employers and the entire human society etc.

#### **4. In conclusion**

As a conclusion to those presented above, there is an apparent preference for the concept of *servicity*, rather than for *productivity* or *performance* (that so rigorously defined by Gallouj and Djellal); in this respect, the answer is very complex: (i) By common productivity, services are considered less productive than the activities in agriculture and industry, but this hierarchy of productivity is not made on the basis of qualitative and creative criteria, but on the basis of quantitative criteria, the productivity indicator itself being a quantitative criterion; in our research, although we did not focus primarily on material sectors; Manoilescu (1986: 100) expressly noticed that labour productivity also implies a certain social dimension); the concept of servicity is more comprehensive than the commonly utilized indicators of productivity; (ii) Servicity involves superior achievements in terms of quality (in the same time unit and with the same effort as in the case of productivity in industry); even if the results of the educational system or political decisions taken with regard to the health care system, for example, are materially unquantifiable, it does not mean that these results do not exist, but they were just not measured, and the related effects will be found over time for the long term and short term, in preparing physicians (and other professionals); the effects of educational and health care systems will be also found in the good and service consumers’ self-education; it will be thus affected; (iii) Servicity implies a value system (Jivan, 2000: 89). In servicity approach, the overall economy is seen both from the consumer’s perspective and from the economic enterpriser’s perspective, taking into account the effects for both sides. Each of the participants should have responsibilities for the other side and, moreover, for the entire social, economic, political environment, and not be concerned only with their own good: self-interest oriented thought can lead to destruction, so, for example, recording a business profit without taking into account whether the business generates pollution or the positive effects are only for the short term and exclusively for the economic entity concerned, thus ignoring any medium and long term negative effects through pollution produced by the degradation of their employees’ health , as well as of other residents around etc. Usually, such effects are not quantified in accounting or in domestic and international databases.

Such indicators can be practically applied for analyses concerning various economic entities, be they material and immaterial, at individual, industry or national level, on different time horizons of interest, allowing complex approaches and being

appropriate for the largest area of scientific concern, thanks to eliminating the routine limits of productivity indicators.

# EVOLUTION OF ENVIRONMENTAL TAX REVENUES IN POST-COMMUNIST EUROPEAN MEMBER COUNTRIES

**Maşcu Simona**

*Ph.D. Student at Doctoral School of the Bucharest University of Economic Studies, Academy of Economic Studies, Bucharest, Romania  
mascu\_simona@yahoo.com*

**Abstract:** *Human activities can have harmful effects on the environment, which may affect the ability of future generations to meet their own needs. Therefore, policymakers must decide which economic instruments should implement in order to achieve the sustainable development objectives.*

*In Europe, effective action demands the collaboration of all economic agents on all member states in order to bring environmental taxation in line with the EU's climate change targets: reducing its greenhouse gas emissions by 20% in 2020 compared to 1990, raising the share of EU energy consumption produced from renewable resources to 20%, and 20% improvement in the EU's energy efficiency.*

*After two decades of post-revolution economic problems and living-standards, some countries from Central and Eastern Europe took the first steps in designing extensive environmental fiscal reforms. The reform implemented in more advanced post-communist countries spread pretty quickly to upper-middle-income and middle-income countries.*

*Through this article, I intended to present an in-depth analysis of energy taxation and an assessment of trends and status of the environmental tax revenues as a share of GDP levied by post-communist E.U. member countries: Bulgaria, The Czech Republic, Estonia, Latvia, Lithuania, Hungary, Poland, Romania, Slovakia, Slovenia by processing the information provided by Eurostat database.*

*Each information is updated and accurate as possible, although that the use of economic instruments for environmental policy is rapidly changing.*

*This article, which is only a work in progress, will conduct further research on a wide range of environmental tax issues. Potential projects will be submitted in publications, article, and conferences. They will cover:*

- *main drivers for the evolution of environmental tax revenue such as final*
- *energy consumption, energy efficiency policies, renewable energy, Europe*
- *Brent Oil Spot price;*
- *the situation of excise duties applied to the most important sources of*
- *energy in relation to the minimum energy tax provided by EU legislation in*
- *CEEC-10;*
- *assessments of the extent to which governments from EU-27 and CEEC-*
- *10 are using environmental taxes; and*
- *entropic degradation – consequences of economic growth.*

**Keywords:** *environmental tax policy; environmental fiscal policy; environmental tax revenues; new E.U. member countries.*

**JEL classification:** *H23; Q50; O57*

## 1. Introduction

Environmental tax policy, which is an indispensable part of European fiscal policy, is employed by governments in order to reduce resulting emissions and to promote environmentally sound products. Environmentally-related taxes are designed by the policy makers such that to be environmental effective. They should ensure fiscal sustainability by achieving revenues and can have distributional implication.

The environmental fiscal policy reform in transition and emerging-market countries of Central and Eastern Europe (CEE) has introduced taxes for environmental purposes, relating to: energy, transport, pollution and resources as European statistics distinguish.

According to the European Commission, an environmental tax is a tax whose tax base is a physical unit that has a proven specific adverse effect on the environment. (European Commission, 2001)

The EU publication "Environmental taxes — A statistical guide" presents several reasons why including the CO<sub>2</sub>-taxes under energy taxes rather than under pollution taxes. "First of all, it is often not possible to identify CO<sub>2</sub>- taxes separately in tax statistics because they are integrated with energy taxes. In addition, they are partly introduced as a substitute for other energy taxes and the revenue from these taxes is often large compared to the revenue from the pollution taxes"

Many countries from Central and Eastern Europe, especially developed countries, have improved their environmental tax policy by introducing new economic instruments with the purpose of supporting and promoting environmental improvements. Therefore, environmental taxes are being increasingly recognized as having the potential to serve as an effective instrument for efficient management of natural resources and to encourage environmentally positive behaviour change. (Deepak Das, 2005)

However, the environmental tax policy had become politically sensitive when the price of mineral oil products increased drastically due to the high prices for crude oil and the devaluation of the euro. (Stefan Bach et al. 2001)

The extent to which environmental tax receipts should have the potential to generate additional government revenues calls for a much closer interaction between environmental tax and government environmental objectives. Thus, the new environmental tax revenues that could be collected may provide an opportunity to increase economic incentives for stakeholders to promote ecologically sustainable activities.

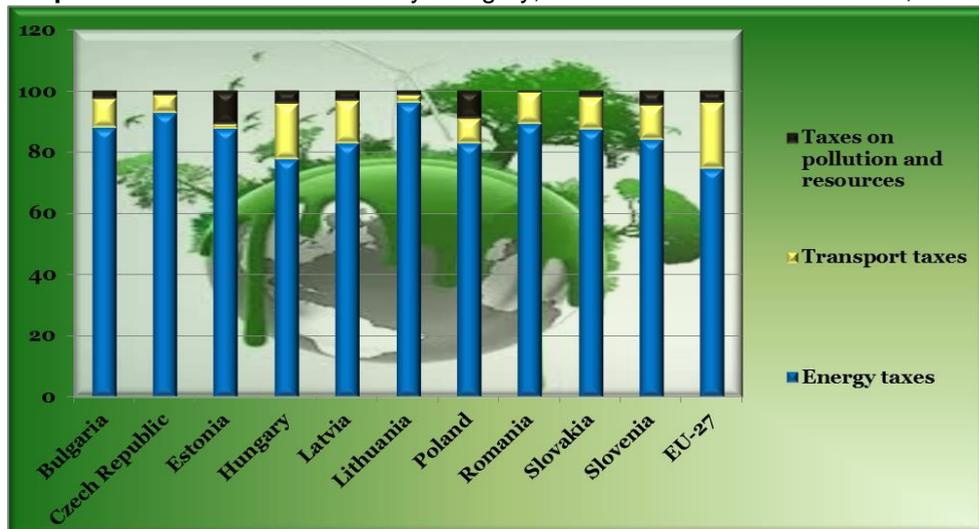

### 1. Trends of environmental tax revenue in total taxation in Central and Eastern European Countries

Further, the discussion focuses on a comparison of 'green taxation' system between European member states from Central and Eastern Europe.

In most post-communist European countries, taxes on energy account for the largest part of environmental tax revenues, between 77,9% (Hungary) and 96,1% (Lithuania) in 2010.

In Hungary, revenue from transport taxes forms 18,1 % of total environmental taxes in 2010, the highest in CEECs. Estonia ranks first in revenue from pollution/resources taxes.

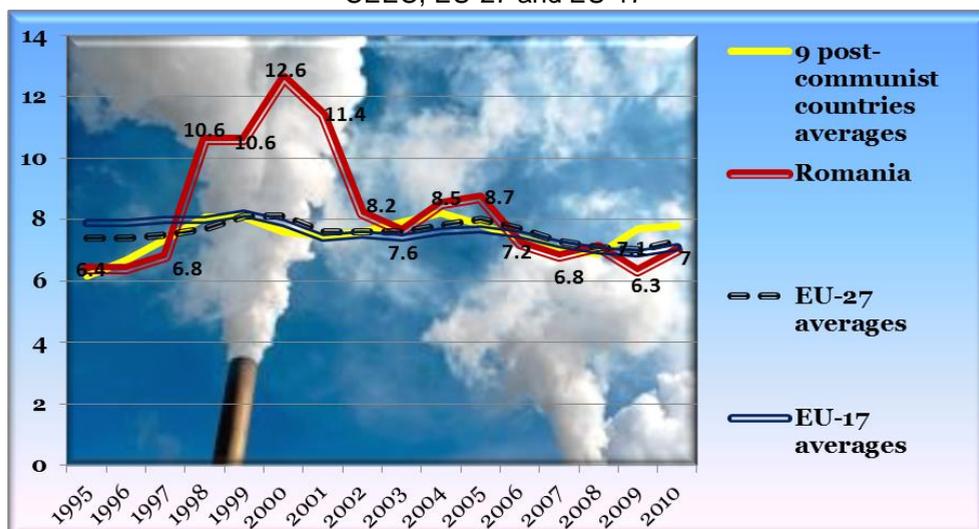

**Graph 1.1.** Environmental taxes by category, % of total environmental taxes, 2010

Source: Own processing of Eurostat data

The share of pollution and resources taxes in total environmental taxes differs a lot across the CEECs, from above 8,5 % in Poland (8,8%), Hungary (10,6%) to only about 1,5 % in Czech Republic (1,5%), Lithuania (1,4%)- see Graph 1.1.

**Graph 1.1.** Environmental taxes as % of Total Taxation in Romania, CEEC, EU-27 and EU-17

Source: Own processing of Eurostat data

In the first decade after communism, Romania recorded a rising trend of the share of environmental tax revenues in total fiscal taxation, thus, between 1995 and 1999 increased almost 6% recording a peak in 1999. This was the highest level of collections from environmental taxes in Europe of all time.

Table 1.1 is focused primarily on the revenues that were raised in Romania in certain years. They can explain the increased levels of the receipts of environmental taxes in a post-communist country between 1994 and 2004. It also describes the main characteristics of the environmentally related taxes, fees and charges in Romania.

**Table 1.1.** Revenues raised from environmentally related taxes in Romania in million Dolar U.S.

Name	Type	Year	Million Dollar U.S.
Air emission non-compliance fees	Fee/Charge	2000	0.3
Fuel excise tax	Tax	1998	0.1
Fuel excise tax	Tax	1999	0.2
Fuel excise tax	Tax	2000	0.2

Source: OECD/European Environment Agency database on environmentally related taxes, fees and charges

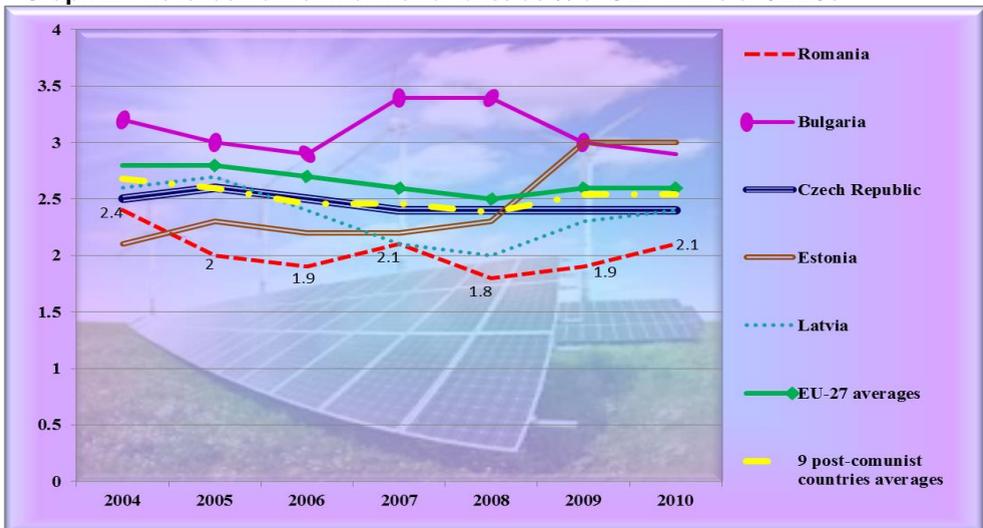

In the analyzed period, Romania raised around 212,2 million dollar U.S., from different green taxes, fees and charges levied by Romanian Government in accordance with European Environmental Agency. Nevertheless, in 2010 Romania raised around 2,5 billion EUR from environmental taxes, corresponding to 2.1% of GDP.

## 2. Comparison between post-communist European countries concerning the ratio of environmental taxes revenue in GDP

This section includes a historical data chart including the ratio of green taxes to GDP of the ten post-communist European member countries.

In CEEC-10, the share of environmental taxes in GDP has fallen between 2004-2008, mainly due to a reduced levels of energy tax revenues, as graph 2.2. shows.

**Graph 2.1** Revenue from environmental taxes as % of GDP in five of CEECs

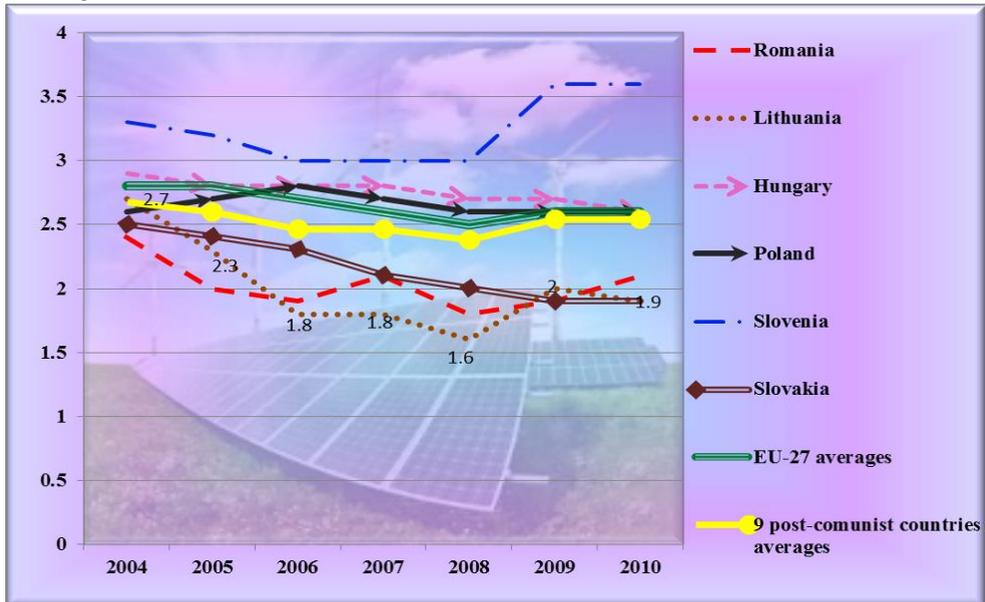

Source: Own processing of Eurostat data

Graph 2.1. emphasize that the aggregate trends in environmental tax revenues in Romania recorded two distinct phases in the prior and post European integration period. In the first phase, the ratio of green tax revenue to GDP dropped, from 2,4 percent in 2004 to 1,9 percent in 2006. In the year when Romania joined European Union, the share of environmental tax revenue to GDP recorded an increase of 0,2 percent over the previous year, followed by a second decrease in 2008. The second phase occurred during the economic crises when green tax revenues increased from 1,8 percents in 2008 to 2,1 percents in 2010.

During the analyzed period, Bulgaria (Graph 2.1 and Slovenia (Graph 2.2.) were the only two countries surpass the EU-27 and CEE averages in respect of the revenues from environmental taxes as a percent of GDP. The Czech Republic environmental

tax revenues recorded a similar trend to that of the CEEC's averages around the amount of 2,5 percents of GDP/

**Graph 2.2.** Revenue from environmental taxes as % of GDP in five of CEECs

Source: Own processing of Eurostat data

During the analyzed period, another two Central and Eastern European countries, Lithuania and Slovakia have had recorded levels of the ratio of tax revenue to GDP below the trend of EU-27 averages and CEEC's averages. Slovakia highest value over the past 10 years was 2,7 percents in 2004 while its lowest value was 1,6 (%) in 2008. Starting from a value of 3,3 percents in GDP in 2004, tax revenue in Slovenia reached a peak of 3,6 percents in 2009 and 2010 in a period of economic downturn and stood there in 2010. The dispersion of tax revenues amount across the ten post-communist European member countries had ranged across time, recording the lowest range (2,38 %) in 2008.

### 3. CEEC-10 Kyoto targets and results corresponding to the first commitment period

All Central and Eastern European Countries have individual GHG reduction and limitation targets under the Kyoto Protocol that should be reduced in two commitments periods: between 2008-2012, and between 2013-2020. Party's assigned amount is the maximum amount of emissions (measured as the equivalent in carbon dioxide) that a country may emit over a commitment period in order to comply with its emissions target.(Kyoto Protocol Reference, European Commission, 2002)

Table. 3.1 Kyoto emissions between 2003-2010, under or above Kyoto target 2010/2012

EU MEMBER STATE	2003	2004	2005	2006	2007	2008	2009	2010	KYOTO TARGET 2012	% 2010/2012 UNDER KYOTO TARGET
ROMANIA	-	160.1	153.7	153.9	152.3	145.9	123.4	121.4	259.9	53.3 %
LITHUANIA	16.7	21.1	22.6	22.8	24.7	24.3	20.0	20.8	44.1	53 %
BULGARIA	-	68.9	69.8	71.5	75.7	73.5	58.9	61.4	127.3	51.77 %
LATVIA	10.7	10.7	10.9	11.7	12.1	11.9	11.0	12.1	23.3	48%
HUNGARY	83.3	79.5	80.5	78.8	75.9	73.1	66.9	67.7	114.9	41 %
POLAND	382.5	396.7	399	399.3	398.9	395.6	381.8	400.9	551.7	27.33%
SLOVAKIA	51.1	49.5	48.7	49.0	47.0	48.8	44.2	46	67.2	22.9 %
CZECH REPUBLIC	147.5	147.1	145.6	149.1	150.8	141.4	134.7	139.2	180.6	22.9 %
ESTONIA	21.2	21.2	20.7	19.2	22.0	20.3	39.2	39.2	40	2 %
										% 2010/2012 ABOVE KYOTO TARGET
SLOVENIA	19.7	19.9	20.3	20.5	20.7	21.3	19.5	19.5	18.6	4.84 %

As Table 3.1 shows nine out of ten Central and Eastern European member countries analysed in 2010. Data for 2010 show that Romania GHG emissions dropped by 24,17% and Bulgaria emissions by 10,88% in 2010 compared with 2004. Although the economy has expanded significantly, emissions have declined, which proves notes the Commission that it is possible to decouple economic growth from emissions

The table details performances by member states: nine out of ten Central and Eastern European Countries – Bulgaria, The Czech Republic, Estonia, Latvia, Lithuania, Hungary, Poland, Romania, Slovakia– had met the targets under the protocol using existing measures, in 2010 compared to 2012 target. Taking into account the information of all available data, Slovenia alone had not met its targets in 2010 compared to 2012 targets, GHG emissions being 4,84% above Kyoto target. In most of the 10 CEEC, emissions has decreased slightly from 2004 to 2010.

#### 4. Conclusions

Focusing primarily on environmental tax revenues, regional environmental tax policy, this study shows clearly how Central and Eastern European countries have improved their new economic instruments, such as environmental taxes. Governments aim to ensure fiscal sustainability with the desire to support and

promote environmental improvements, by collecting tax revenues.

Ten years after EU enlargement, the new member states from Central and Eastern Europe have been hit by the current economic and financial crises which has been characterized by more or less turbulence in different countries.

During the analysed period, we can see that in post-communist European member countries as a whole, environmental tax revenues (as % of GDP) were situated well below the EU-27 averages. This may be a result of uncertainty and unpredictability of environmental tax revenues, and, in particular, their erosion as a result of the behavioural responses of polluters and final consumption compression.

As The revenue from pollution, resources, transport taxes may be affected by behavioural responses. (Don Fullerton et al. 2008) Energy taxes, fuel taxes might be less affected by behavioural responses than other environmental taxes due to their inelastically-demand commodities.

In respect of increasing environmental taxes, Governments should take into consideration the negative impacts of environmental taxes on competitiveness of different economic sectors and income distribution of households.

Environmental taxes should be levied to more detailed environmental issues, such as energy consumption, toxic waste, sprawl, water and air quality, and habitat protection.

**Abstract:** *The granting of credit, whose excessive diffusion was one of the causes of the economic and financial crisis of 2007, has suffered profound changes during the following period of economic recession. The granting of credit to households and businesses has been strongly influenced by the effects of the economic downturn, the banks' choices and the intervention of the supervisory authorities. The credit, however, is also an instrument of monetary policy through which governments and central banks try to stimulate the economic growth. There are, nevertheless, several and complex limitations to the actions of banks and other financial intermediaries, information asymmetries and structural limits of the credit market. Should also be considered that in many Countries the economic recession had a strong influence on the choices and opportunities for all economic agents, making it difficult to lay the foundations for economic recovery. In the previous years, the lowering of standards of borrowers and the presence of low interest rates, setting the conditions for the so-called housing bubble. The subsequent reactions, the general worsening of the economy, the lack of funding and liquidity, in addition to the strict rules imposed by the supervisory authorities, have led banks to tighten securely controls on the characteristics of borrowers, being also obliged to put more attention on the composition of the balance sheet. Under these conditions, have risen subjects that do not meet the requirements to receive funding, and at the same time increased the difficulty to repay loans and interest. In this paper a multidimensional scaling analysis is used to observe the situation of credit in the Italian regions before and after the outbreak of the crisis, considering the average values for nine variables and for two different period, before and after 2007. Searching for dissimilarity between areas of the Country, is highlighted a clear separation before the crisis and remained essentially unchanged between northern and southern regions. Furthermore the analysis of time series showed that the granting of credit has declined slightly, but above all has changed destination, from productive purposes and investments, to support consumption.*

## 1. Introduction

The rationing of credit by banks is a phenomenon that occurs when some characteristics of the business cycle interfere on the work of financial intermediaries. There are several reasons that limit the grant of credit, but in general it can be stated that it can find its origin in the so-called information asymmetries and limits to the action of lending institutions. The greater rigidity in the granting of credit to households and businesses characterize recession periods and is due to many causes which in some cases are mutually reinforcing. Authorities' actions in the regulation of the financial sector, in addition to the difficulties which have arisen in the balance sheets of the banks, and the lack of liquidity, may induce the so-called marginal borrowers to be unable to restructure their debts or obtain new financing. This is a case where there is a risk of still more defaults, as well as those caused by the general economic slowdown.

The credit is seen as a channel of transmission of monetary policy and makes it possible to amplify the effects of although small shocks as a result of the macroeconomic policy, also due to the imperfections of the credit market. As well as an instrument of monetary policy transmission to real economy, the credit plays a fundamental role in supporting economic growth with obvious links on the levels of investment and consumption. Among the leading causes of the so-called credit crunch there is the increase in the perception of the risk of insolvency, the latter that has been one of the reasons of the financial crisis of 2007.

The restriction, at certain levels, would be detached from the consideration of the rates charged, at least for specific types of borrowers. This discrimination and the banks' choices have been explained with information asymmetries, in particular through the process of adverse selection, considering an increase of the risk of default associated with the increase of the interest rate. In this condition, the banks establish a maximum limit of convenience of the rate at which make loans.

Many factors affected the market of loans from the banks side: the scarce availability of loanable funds, the decrease in the equity capital, the expectations of financial intermediaries, the securitization of some assets present in the banks' balance sheet. Furthermore, the worsens general economic situation obviously influences the conditions of many borrowers and potential ones. The economic recession leads to a decrease in the demand of credit, but also in the markets of investments and durable goods (Bernanke et al., 1991).

The explanation of the triggering causes of the economic and financial crisis of 2007 is illustrated, among others, by Brunnermeier (2009). As known, the so-called "housing bubble" has grown in a context of low interest rate influenced both by the decisions of the *Federal Reserve* and from capital inflows, in particular from Asian Countries to try to control the depreciation of national currencies to the dollar. In the same years was developing a model of behaviour of banks which did not involve more the traditional cycle of the loan. This was not to wait for the expiry of loans, but to split and to incorporate them into structured products (with different levels of risk) offered to financial investors.

This of course allowed to rebalance the composition and the risk of the balance sheet of banks. Obviously this involved the move out of the direct responsibility of the banks of large part of the risk, and therefore the same banks could lend more easily to borrowers.

So even subjects without personal guarantees could obtain funding for the purchase of properties, which were guaranteed by the fact that the value of the real estates

steadily increased (and therefore often mortgages were higher than the actual value of the properties). This growth in turn was influenced by the demand made possible by the low rates and the minimum quality standards for granting mortgages. The collapse of values because of what happened during the 2007, after bubble burst, became a reason not to compensate the creditors.

The generalized deterioration of the economy may even threaten the existence of weaker banks, due to the composition of the ratio of capital owned and assets hold, and of course different level of risk involved in the same assets. The greatest risk is for the banks that have a large amount of assets characterized by the possibility of losing their value, such as loans granted to companies, but also equities and bonds. In the case of economic recession, to prevent these complications, the authorities may intervene to regulate the financial market, imposing different and more stringent limits to the work of banks, new rules that involve a more careful selection of the composition of their capital and assets. These interventions serve to protect the system by intervening especially towards the banks at greater risk, as mentioned because hold a lower share of capital of property and a high proportion of assets at risk of losing value. Bernauer and Koubi (2002) analyse the dilemma of the two possibilities, restriction of credit or bank default, searching for the best solution to limit these two possible problems for the economy. So the dilemma arises from the point of view taken in the regulation. It is possible to pay attention to the short term, avoiding the credit crunch, to prevent a worse financial and economic situation. Moreover the authorities can't risk the so-called banking panic caused by the failure of weaker banks, or even the risk, and decide to intervene with stronger prudential requirements. In this situation, banks should limit the granting of credit to meet the more stringent rules. This would tend to intensify the already difficult economic situation by creating more problem for the activities and needs of companies (Bernauer and Koubi, 2002). Furthermore, the fact that the restriction does not allow the marginal borrowers to refinance their debts, risking bankruptcy, in turn induces an additional problem for the banks to which they can't refund loans (Woo, 2003). In addition, banks may fear for the future hoarding of capital, and then push to accumulate funds immediately. Another reason is the need to hold additional funds and the difficulties that are created by network effects, when banks are both creditors and debtors to other institutions and this shall create worries about the credit risk of the counterparty and this doesn't allow to erase positions of opposite sign (Brunnermeier, 2009). Of course, the uncertainty and the scarcity of private savings also make more difficult for the banks to find new resources, for example through the issue of bonds.

The paper, after this introduction, presents a paragraph on the scientific literature regarding performance and problems related to credit during economic recession and post-crisis periods, followed by a description of the European context and the observation of time series data on the Italian credit to analyse the evolution of various categories. The differences between the regions, in terms of average credit concessions to households and companies, before and after the crisis, are subsequently examined, by using a multidimensional scaling analysis at regional level.

## **2. Monetary policies and effects on credit**

The issues that led to the credit crunch have various sources. The trend in the flow of credit, expansions and contractions, suffers changes connected with the

economic cycle and for Dell'Ariccia and Garibaldi (2005) the behaviour of changes is asymmetric, resulting in the higher volatility of credit contraction than credit growth.

This lead to define the credit crunch as a typical characteristic of cyclical downturn, as observed by the Authors after the 1991 recession. In addition, the net changes of the credit are composed by different types of operations that are credit contraction and expansion, for the banks a commitment on at least two fronts: efforts to recover risky loans and the need to select new debtors (trying to reduce informational asymmetries). The fact that contraction is more volatile than expansion and takes place during periods of recession of the cycle, and the observation that excess credit reallocation is negatively correlated with the fluctuations of *GDP*, suggests that the strengthening of the credit crunch in negative periods of the economic cycle has dissimilar explanations compared to expansion, that happens in the case of cyclical upturns (Dell'Ariccia and Garibaldi, 2005). On the role of the credit channel as a propagator of initial shocks also Balke (2000) in an analysis of the credit conditions as a nonlinear propagator of shocks. The Author proves that shocks are more effective in the tight-credit regime, furthermore there is a different effect of monetary variations, whereby the contractionary ones have a higher effect on output than expansionary shocks.

As mentioned before, we must consider the presence of the imperfections in financial markets in the two main channels of transmission of monetary shocks. The two channels used by monetary policy are the bank-lending channel and the broad credit channel (or balance sheet) (Bernanke et al., 1996). The first one considers the imperfections caused by informational asymmetries between the lenders and the borrowers. The principal role is played by the premiums that are required for the funding, furthermore the operations of open market of the central bank, modifying the lending possibilities of banks, have direct consequences on the customers' necessities of renovate or ask for new funds. The second channel, of the broad credit, is instead founded on the dissimilar characteristics of debtors, usually considered as firms. The balance sheet plays a determinant role on the fixation of premiums and a contractionary monetary policy usually induce a worsening condition for the same balance sheets. This situations produce an increase of the original shock.

The ineffectiveness of monetary policy can derive at least from a couple of reasons, the liquidity trap hypothesis and the credit crunch hypothesis. Woo (2003) observed the two hypotheses on the case of recession in Japan. The first one is due to the simultaneous presence of high real interest rates and nominal interest rates near zero, making it impossible for the central bank to further act.

The increase in the money supply and the decrease in interest rates should stimulate the demand, which in this case is braked by negative expectation about the future, that induce an increase in savings, with negative consequences on investment and consumption. Furthermore, the intervention on reserves and the above mentioned reasons about credit crunch can lighten the real effects through the credit channel, which should translate the original expansionary monetary policy. The credit crunch hypothesis consider instead the lack of capital available to banks to grant more loans, despite low interest rates, slowing therefore transfer channels of monetary policy.

Of course, in the performance of credit must also be considered that each bank independently determines the requirements that a subject must possess in order to

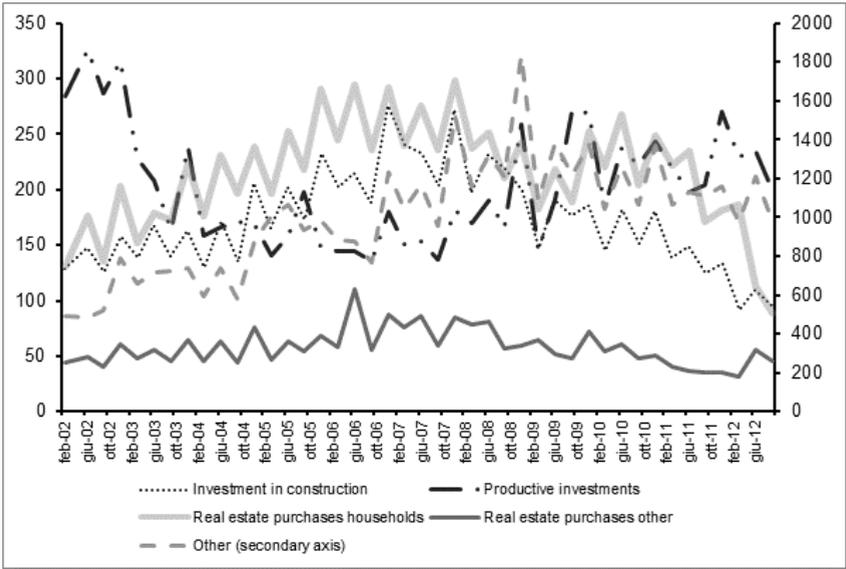

be eligible to receive loans. Gorton and He (2008) note that such competition between banks induces endogenous periodic cycles of credit restrictions. The Authors observe the phenomenon as a repeated bank lending game, based on publicly available information and on the assumptions of the behaviour of other banks. Consequently the models used by banks to take decisions and then the changes in the amount of loans granted are an autonomous source of macroeconomic fluctuations.

### **3. The condition of credit in Europe and the Italian case**

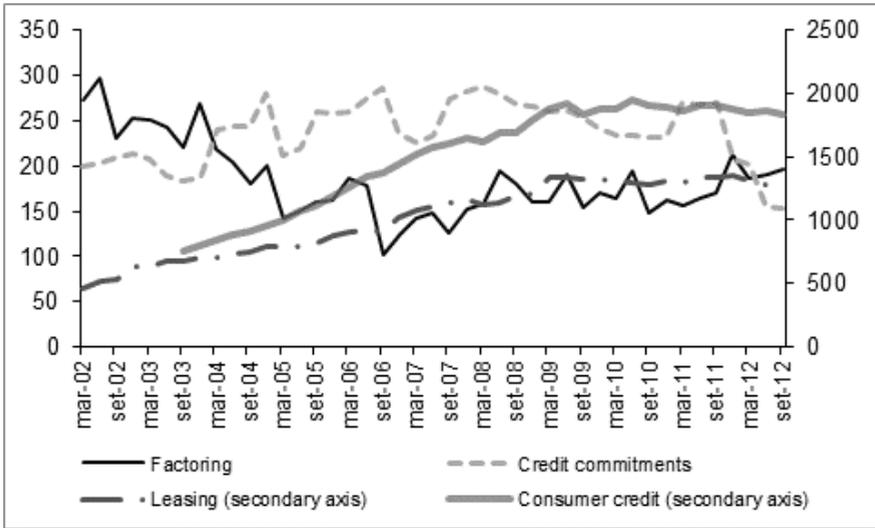

The first complications, caused by the inability to collect ranked subprime mortgages, occurred since 2007, and then the first signs of illiquidity on the interbank market. Liquidity decreases when it becomes more difficult to share the risk and hard to raise funds, or sell assets on the market (Brunnermeier, 2009). The *European Central Bank* and the *Federal Reserve* did intervene by lowering interest rates and injecting billions of euros and dollars into the interbank market credit to lessen the liquidity crunch. Monetary injections in the system may generate an effect of liquidity resulting in a positive effect on the availability of credit to households and in general on real activities (Li, 2000). The cost of financing in cases of necessity by banks is a key factor on the choices of liquidity. In Europe, the intervention of the *ECB* was intense especially in Italy and Spain, two Countries hardest hit by the recession and where the granting of credit to households and businesses was greatly diminished. The European situation has been worsened by the general undercapitalization of banks, as well as difficult circumstances for companies and households. All of these economic agents in difficulty must focus their attention to repay debts rather than borrow to invest and consume. In this study we use data on credit from *Banca d'Italia (Bollettino Statistico, 2002-12)*, at regional level and covering the period 2002-2012. As said, Italy was one of the Countries most affected by a series of negative conditions, which have imposed a severe recession and a general slowdown of economic activities. The absence of growth prospects simultaneously caused the postponement of productive investments and decreased business profitability.

With the details of the data used we can see differences and specificities of different areas and observe the influence of the economic crisis on the different variables of the credit. In the following two graphs we observe the time series of nine variables related to credit granted in Italy (2002-2012).

All values are in euro per capita, using data for population from ISTAT. In the first chart there are five types of financing over the short term, new disbursements for each quarter; in the second chart other four variables regarding the performance of the credit.

**Figure 1:** Different types of funding over the short term in Italy, per capita values in euros (2002-2012)  
 Source: Our elaborations on *Banca d'Italia* data

**Figure 2:** Four types of credit and collateral in Italy, per capita values in euros (2002-2012)  
 Source: Our elaborations on *Banca d'Italia* data

The observation of the time series of the various types of credit over the short term (Fig. 1) show that the total level has suffered a decline from 2010. Absolute values were affected by the sharp fall of investments in construction at the end of 2007, while the productive ones showed a slightly positive trend. The purchase of real estate by households and other property, had, considering the absolute values, a

stable trend, adversely affected just during the 2011-12 period. The last and largest category, all the other destinations of funding over the short term, show an upward trend until the end of 2008, and then stabilized. In the second graph (Fig. 2) are shown the growth trend of consumer credit and leasing, typically two types of credit to support consumption. Factoring showed a reversal of the trend, that was negative before 2007, probably to try to get anticipations on credits by businesses. Finally, the credit commitments, then a type of collateral by banks, it is observed in stable trend, with a sharp decrease after the third quarter of 2011. The performance of the four variables just described (Fig. 2) indicates a stop to all increments after 2007, and the emergence of a stability in 2010-11 in the values of credit specifically aimed to businesses and productive investment, due to economic recession. In summary, the proportions of credit to productive activities and investment have changed, particularly to credit addressed to maintain previous levels of consumption, otherwise in decline also for the level of unemployment. This has made possible that consumption not collapsed, with a support on GDP, but of course lacking the foundations for economic recovery.

#### **4. Data, methodology and results**

To reach our purpose, which consists in identifying the trend of granting of credit in Italian regions before and after the outbreak of the financial and economic crisis and the implicit consequences set forth in the preceding three paragraphs, we use a multidimensional scaling analysis. It is a useful tool through which it is possible to produce a graphical representation of a pattern of objects, in this case the 20 Italian regions, based on the degree of similarity/dissimilarity between them. The goal is to provide a representative map that best approximates the distances observed between the same regions, concerning the availability and the granting of credit in its various forms and purposes. This statistical method attempts to build a configuration of the various entities, merged in a small number of dimensions (two in our case). This is done by defining relations between regions in terms of proximity/distance with respect to the considered indicators. The resulting positioning map has the property to partition the regions into homogeneous groups, so as that the degree of association between two regions is maximal if they belong to the same group and minimal otherwise. We considered a matrix of 20 regions (plus the aggregated data for Italy) and indicators, representing 2 sets of variables: various types of credit extended over the short term, other important types of credit to households and businesses (see Table 1). In particular, we have selected the following indicators (source: *Banca d'Italia*): new credit disbursements over the short term (investment in construction, productive investments, real estate purchases households, real estate purchase, others), leasing, factoring, credit commitments, consumer credit. Data refer to the periods 2002-2004 and 2009-2012 (mean value for the two considered periods). Data were rescaled between 0 and 1 within each considered variable, in order to avoid possible distortions due to different ranges and magnitudes.

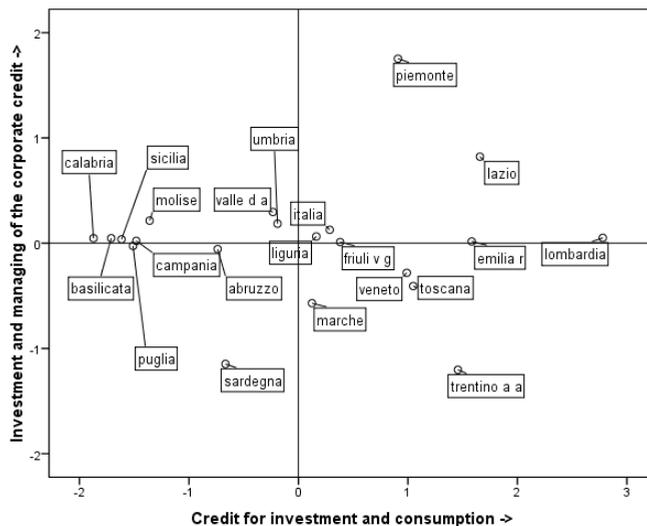

The model's goodness of fit was assessed via the RSQ (0,96 both for the first and the second considered periods), that indicates the proportion of variability explained by the corresponding dissimilarity distances, and the Stress Index (0,10 both for the first and the second considered periods). As a general rule, results are found to be robust when the size  $k$  achieves an Stress Index value lower than 0,15. A two-

dimensional model was judged to be acceptable according to the values of the previous indexes. The correlations between dimensions and variables for the two considered periods (see Table 1) were useful for naming the axes. The resulting two-dimensional images are shown in Figure 3 and 4. The horizontal axis, the most significant and representative, represents for both graphs the variables concerning the credit over the short term and the households; the vertical one is related to investment and managing of the corporate credit in the first graph, and to consumer credit in the second one.

**Table 1:** Correlations between variables and dimensions ( $r > |0,6|$ )

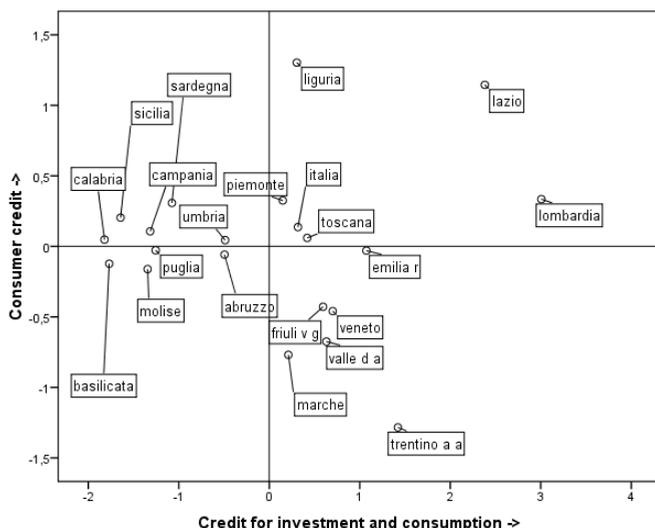

Variables	2002-2004 configuration		2009-2012 configuration	
	Dimension 1	Dimension 2	Dimension 1	Dimension 2
Invest. in construction	0,80		0,80	
Productive investments	0,62	0,70	0,79	
Real est. purc. househ.	0,92		0,93	
Real est. purchase other	0,87			
Other (over short term)	0,95		0,95	
Leasing	0,88		0,89	
Factoring		0,75	0,69	
Credit commitments	0,89		0,89	
Consumer credit	0,80			0,63

Source: Our elaborations on *Banca d'Italia* data

**Figure 3:** Cluster of regions in a two-dimensional space (2002-2004)

Source: Our elaborations on *Banca d'Italia* data

**Figure 4:** Cluster of regions in a two-dimensional space (2009-2012)  
 Source: Our elaborations on *Banca d'Italia* data

The two graphs above show the situation remained almost unchanged before (2002-2004) and after (2009-2012) the advent of the economic downturn. Observing the first dimension in both graphs, significant to understand the average values of credit to households and businesses, it shows a clear distinction between the northern and southern Italy, remained stable over time. The group of the northern regions has higher values for all types of credit, indicating a greater entrepreneurial vitality and possibility of consumption for households. Between these regions there are also outlier cases for the second dimension. In the period 2002-2004, Piemonte region has in fact high values for both the two variables considered (see Tab. 1), productive investment by firms, much higher than the national average, and factoring, also related to businesses and to the possibility to receive advances on credits. The second graph shows in particular the low use of consumer credit to finance purchases by households in some northern regions, as Trentino, Valle d'Aosta and Veneto, on average higher in the centre and south of the Country.

## 5. Conclusions

The economic crisis, emerged following the bursting of the speculative bubble in the U.S., was largely caused by previous alterations in the procedures for managing of credit by the banks.

There have been several causes, related to each other, which affected the possibility to provide credit and then to be the basis for economic recovery: interventions of the supervisory authorities, monetary policies, problems of banks' balance sheets and the general deterioration in economic activity of households and firms.

Our analysis, based on data on several types of credit concerning the Italian regions, for the period 2002-2012, has shown that there has been a contraction of credit, as expected by the theoretical and empirical studies, at least for certain types of loans,

such as those of the relevant construction sector. This restriction is due both to banks' choices, such as increasing requirements of borrowers given the increased risk of default, and also for the lack of liquidity and the stringent rules in order to avoid the risks of failures.

Other forms of credit to businesses, and even more for households, are increased after the crisis, or remained unchanged, thus marking a shift of these resources to support consumption, which would otherwise have been adversely affected by the crisis. Moreover, in Italy, before and after the outbreak of the crisis, remained a strong distinction between the southern and the northern regions, the latter with higher mean values for all the nine types of credit considered, with more possibility to receive funding, that for companies means more opportunities to invest and improve the local economy.

# IMPACT OF ECONOMIC CRISIS ON PUBLIC SERVICES OF SOCIAL VALUE IN ROMANIA

Milin Anda Ioana, Ciolac Ramona, Radac Bianca, Fruja Ioan

[anda\\_milin@yahoo.com](mailto:anda_milin@yahoo.com)

[ramonablaga2005@yahoo.com](mailto:ramonablaga2005@yahoo.com)

[biancaalinaradac@yahoo.com](mailto:biancaalinaradac@yahoo.com)

**Abstract:** Public services market is closely linked to the involvement of the state in economic and social life. The extent and modalities of involvement varies from one country to another, from one period to another are influenced by many specific factors concrete. With the involvement of the state in economic and social life goals should be considered or - declared or not - -especially those interventions effects on the community and individuals. The paper starts from the idea that public service education, the health care and social services ensures the physical and intellectual integrity of the individual, regardless of his income level. In democratic societies are more and more talking about education as the means of personal development, a service available to all, regardless of social class, religion, gender, and access to health care is considered a basic right of the individual. Medical services should be seen as a means by which many social objectives can be achieved in the long term (equal opportunities, financial security during illness) not as simple care of the sick. The paper includes analysis related to: the structure of social protection in our country, the scope of these services, the relationship between social protection and poverty, the way and the degree to which social protection deepens or contribute to poverty reduction. The economic crisis triggered in Europe in 2008 that also affects Romania, negatively influenced the evolution of social funds in key areas of public interest, education, health and social care. This results from: decreasing share of social spending in the state budget, decreasing share of these expenses in the total family budget due to lower purchasing power and thus the obligation of individual to reduce or waive some costs of this kind, central and local government bodies inability to meet certain service requirements such at the level of the population and especially low-income population groups. Located in the crisis situation the state must seek solutions to keep social services at an appropriate level because the quantity and quality of these services have an impact upon quality of life and standard of living of many individuals. The results of the analysis indicates us a reduced benefit for this type of service, in our country, with negative effects over the entire society. The conclusions aim to support the fact that social policy from our country is insufficient in relation to the real needs of the population, being strongly influenced by domestic economic situation and the size of the global economic crisis.

**Keywords:** public administration, economic policy, market distortion, social protection

**JEL classification:** H50

## Introduction

Services we analyzed in this paper are general and affect different population groups, constituted from the most diverse criteria. In these circumstances there are individuals and

social groups and disadvantaged, with limited access to some of these services, for reasons more or less objective.

The paper analyzes the evolution of government spending for major public social services in Romania, education, health, social insurance for the elderly through pension fund in 2008-2010. The level of state spending for such services affect the quantity and quality of services. We also made some predictions regarding state budget expenditure on this sector for 2013, based on the Government Program. The paper was developed based on the study and interpretation of statistical data provided by the specialized bodies in Romania and the European statistics regarding the situation of these services from economic crisis to the present day.

### **Research results and discussion**

Public administration has a certain mission, purpose and responsibilities that reflect upon social life. When referring to Romania where public administration is organized on two levels, central and local. The panel is composed of ministries and other central agencies and the local works being based on Romania's territorial organization, communes, towns, counties. There is a clear link between the state (government), administrative services (public) and public policy. Public services are services that provide collective benefits in the general interest of the community (army, police, justice) or directly to that benefit of the individuals (education, health, social welfare). Public policy analysis is, in general, an approach that identifies with programs of action of public authorities in a given area of activity. The term can be used depending on the items that want to be highlight (educational policy, health policy, literacy, non smoking, environmental etc). Public policy in contemporary society:

- is a group of decisions taken at different organizational levels, macroeconomic, meso and microeconomic

- Can take several forms (programs of political parties, especially with the election through legal regulations (laws, emergency ordinances, accountability, local government decisions);

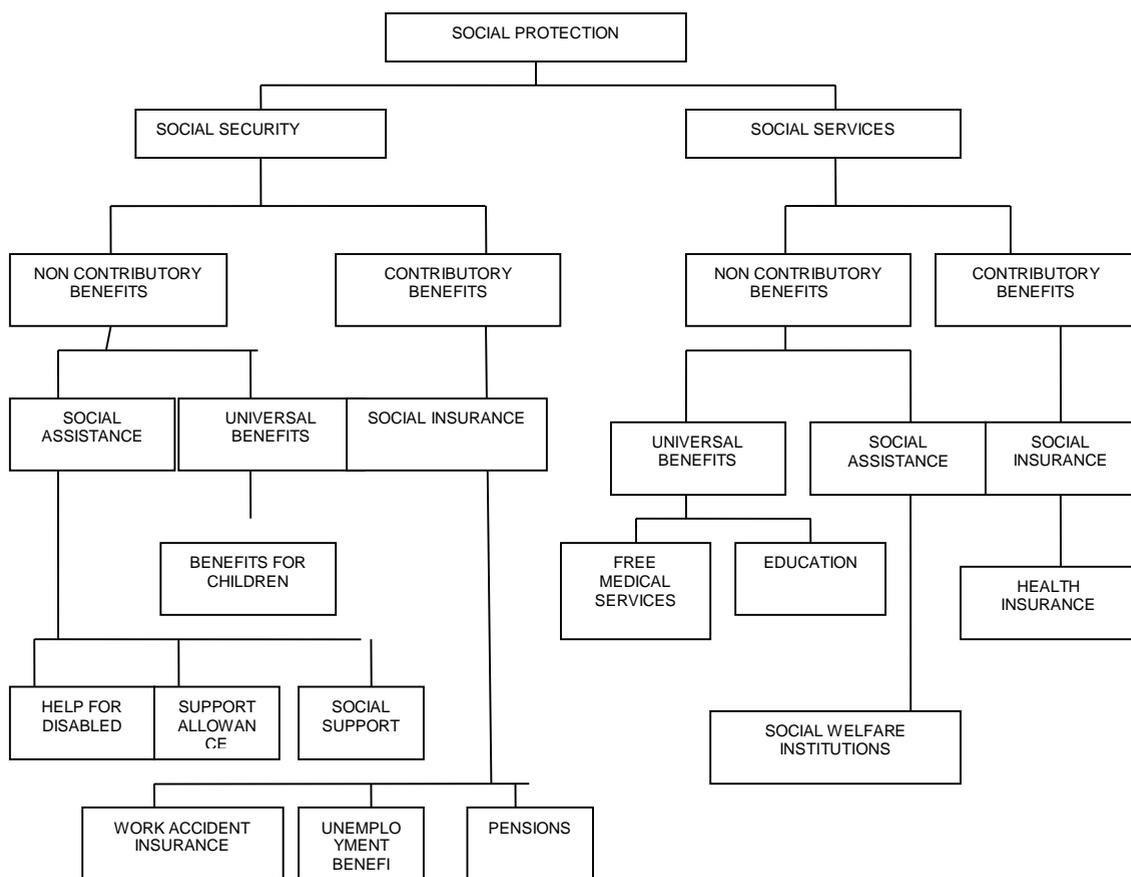

- Mobilize adequate resources to ensure the provision of these services;

follows a general-purpose oriented towards satisfaction of interests, is the carrier of certain values.

Guy Peters defines public policy as "all activities that directly or indirectly affect citizens, which operates on three levels- public election, the results of policies, policy impact" (G. Peters, 1993). Also public policy "is a set of measures taken by the legal and responsible authority that aims to improve the living conditions of the citizens ....." (Profiroiu M., 2006). The social policy is part of public policy. It consists of various benefits and social services. They are designed to cover the full range of basic needs for all segments of social, occupational or age. The ensemble of benefits forms the system of social protection that consists of:

- universalistic benefits (social services) - granted to all citizens, as "deserve goods"without being a situation of risk (compulsory free education, free health assistance)

- Services provided to disadvantaged groups to allow them to meet the minimal needs (social support of various types-for example subsidies to cover services related to utilities that can not be supported entirely from revenues).

**Figure 1- Social Protection System in Romania**

Source: author's construction based on Ministry of Finance Newsletter 2010

We chose to analyze over the work from the social security system and pension related expenditures in the state budget and from the social services the one from the health service and free education and expenditure on social and state funds but going beyond its types services.

Schematically social protection system in Romania can be outlined as follows (Figure 1).

Pension system has the main objective to provide a permanent replacement income over a certain age and protection in the event of special circumstances generating temporary work incapacity.

In Romania public pension system is mandatory, largely system "step-by-step payment." Under the new pension regulations it is proposed national pension system on three pillars:

- pillar I requires a public pension and mandatory;
- pillar II requires a public and private pensions, mandatory;
- pillar III requires private pension system, which is not mandatory.

Analyzing statistical data presented in the following table can do the following findings: number of pensioners in the period 2008-2010, declined slightly by 26,000

people, in case of pensioners from the state system was decreased with 52,000 people and in the case of farmers with 129,000 people.

**Table1** Average number of pensioners (mii persoane)

	1990	2000	2008	2010	2010/1990 (+-)	2010/2008 (+-)
Social insurance pensioners-total	3577	6110	5701	5675	+2098	-26
Social insurance pensioners (without farmers)	2570	4359	4819	4767	+2197	-52
Social insurance pensioners – farmers	1007	1751	866	737	-270	-129

Source: National Institute of Statistic (INS), Anuarul Statistic al României, 1991,2001,2007,2011

People should understand that for the future, the pension provided by social security is not enough, but is designed only to cover living expenses and therefore they must think more seriously about private pension plans. The most important issue is the level of education and information of the population, which has already begun to work, but it can be improved for the purposes of initiating campaigns on the utility, the need to use complementary private schemes that would bring the individual finally a supplementary pension. Monthly average pension represented in our country in 2010, 41.7% of the average gross wage on economy, having an average of 716 lei per month (170 euros) down from 2009 when it was 44.8%. The cause is the non index of pensions in relation to the average growth of gross salary and nor with the inflation rate. In 2010 returned in average 1.3 retirees per employee. Income from social benefits were accounted for 25.7% in 2010 from the total income of a family household (total families) having a weight differential, namely:

- 6.5% In the case of a family of employees
- 14.3% For family farmers
- 27.1% For unemployed families
- 55.2% In the case of pensioners

These revenues increased compared to 2008, when they represented 21.6% of total income of a household. In the case of employees were 5.3%, 22.6% the unemployed, 49.5% of pensioners being smaller in the case of farmers, only 15.1%. A certain level of income may be an indicator for assessing the degree of poverty thus poverty level can be assessed according to the size and average monthly income / family. In Romania, in 2010:

- 26.9% of families had a monthly income of up to 349 lei meaning 82 euro / month on witch revenues / day for a person were euro 2.73;
- 37.1% of the families had a monthly income of up to 434 lei, meaning 102 euro, and the daily income per person was 3.4 euro
- 16.5% of the families had an income of over 1,048 lei per month, meaning 244 euro, the average / person. So a daily income of 8.24 euro.

Level of these revenue highlights an increase of the gap between rich and poor, Romania being found among the nations with the highest level of poverty in the EU, 29.4% of all households. Ratio between average daily income / person from the best situated families meaning 89.24 euro and those with the lowest income 2.73 euros was 3/1. Compared with our country, the poverty level in the EU is as follows:

- Less than 5% of the poor population was register in Sweden, Finland, Denmark, the Netherlands, Austria, Spain;
- Between 5-10% poor population-Great Britain, France, Czech Republic, Slovenia, Portugal, Estonia;
- Between 10-20% - in Poland, Hungary, Slovakia, Greece, Lithuania;
- Over 25% poor population, Romania, Latvia, Bulgaria

Poverty varies from one European country to another and therefore has no value in euro / person. (Adevarul 6853/10.01.2013)

The poverty level in Romania is also confirmed by statistical data from semester 3 of 2012:

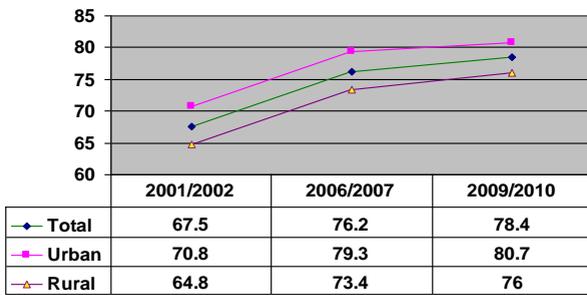

- Average monthly income / household was 2457 lei, meaning 551 euro and 856 lei/ person, meaning 192 euros.
- Per person income in Euros / day was 6.4 euros.
- Expenses of the households in the same quarter represented 90% of total revenues, highlighting a different facet of poverty, the level of these expenses increased by 5% compared to Quarter 3 of 2011. (Adevarul 6852/09.01.2013 and preliminary data NSI 2011).

The economic crisis has affected education services. In no year after 2008 the education did not receive accordance with the provisions 6% of GDP but much less, meaning 3.6% in 2008-2010. The share of education spending in GDP during this period placed Romania on the place 38 of 41 states recorded statistically in the countries of Central and Eastern Europe that allocated a higher percentage of GDP for these services-Estonia-6, 1% Latvia-5, 8%, Hungary-5, 5%, Bulgaria-4, 7% and well below the level of advanced EU countries: Cyprus-7, 9%, Denmark-7, 77%, Ireland-6, 6 %, Belgium-6, 4%, Sweden-6, 5%, Belgium 6.4%. etc. (INS Statistical Yearbook of Romania 2011). Analysis of statistical information about the education system in the range 2008-2010 allowed us to draw the following conclusions:

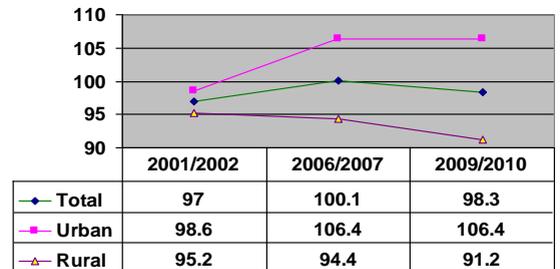

- Has decreased the number of administrative and auxiliary staff from education but also teaching staff from primary, secondary and vocational education, the trend was highlighted in the academic year 2010/2011.
- The share of skilled personnel is however an upward trend;
- Report student / teacher ratio was 11 pupils / teacher ratio in secondary education to 17 students / teacher in preschool and primary education;
- Overall school population of Romania is declining (and population);
- More and more children are pre-school (91% of children that entered first grade attended kindergarten);
- Almost 80% of school-age population 7-23 years is included in the educational system;
- The last three years participation in higher education;
- Participation rate of adults, 25-64 years in education and training is decreasing, in 2008 it was 1.6%, four times lower than the EU average (Government of Romania, Report on the educational system in 2010 ).
- the material and educational services in rural areas are the most affected by spending cuts in this area.

Material facilities rural education, expressed in quantitative terms, does not seem unfavorable, but in qualitative terms only the analysis in qualitative terms highlights the serious issues of educational services from rural and the gap between this type of services provided in rural and urban areas. In most part of the communes (90%), the educational process is carried up to secondary school level (in some cases only

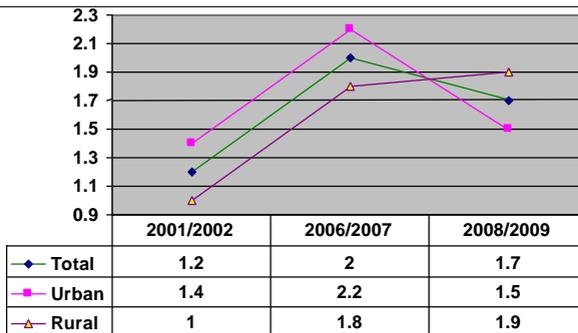

up to primary level), institutions of secondary or post-secondary level are very reduced in number from rural. Under these conditions rural students travel long distances to attend secondary school in some communities or towns in the area. School drop registered in rural areas is mainly due to increasing poverty in rural areas. Statistics on school attendance in rural areas has enabled us to draw the following synthesis, expressed graphically.

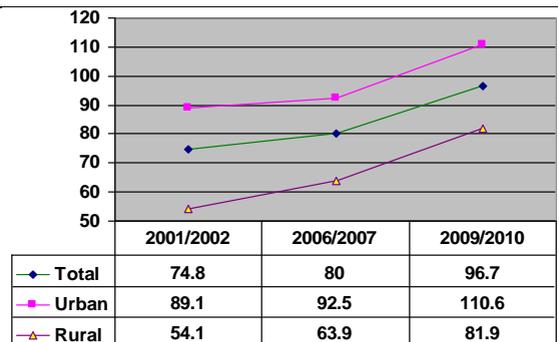

**Grafic nr.1**-Gross rate enrollment in early education in rural and urban

**Grafic nr.2**-Gross rate enrollment in primary and secondary education in rural and urban

**Grafic nr.3** -The dropout rate in primary and secondary education

**Grafic nr. 4**-The dropout rate in secondary and vocational education

Source:\*\*\* Government of Romania, 2010 Report on the educational system

Analysis of free medical assistance services and health infrastructure were influenced between 2008-2010

- Departures from state health system of numerous medical professionals
- closure of hospitals and health centers, especially in rural areas or smaller towns, especially after 2010.

Health expenses for in 2010 were accounted for only 2% of total expenditures. In the same year came back 24.4 physicians to 10.000 inhabitants and 6.2 beds in hospital per 1,000 inhabitants.

Between 2008-2010 the evolution of medical personnel was as follows:

**Table 2** Evolution of sanitary personal

<b>Denumire</b>	<b>2008</b>	<b>2010</b>	<b>2010/2008 +-</b>
Inhabitants/Doctor	428	411	-17
Doctors at 10.000 inhabitants	23,4	24,4	-1
Inhabitants/Farmacists	1837	1573	-264
Farmacists at 10.000 inhabitants	5,4	6,4	-1
Inhabitants/ ward staff	162	169	-7
Ward staff at 10.000 inhabitants	61,6	59,1	-2,5
Ward staff/doctor	2,6	2,4	-0,2

Source: National Statistics Institute, NSI, Romanian Statistical Yearbook 2011

Current government program for 2013 takes into account registration of slight progress or maintain the same level of social expenditure, taking into account maintenance or slight reduction of the phenomenon of economic crisis. According to the national budget, the total GDP of Romania planned for 2013 will be 140 billion euro, of which social security benefits will be at the following levels:

- Pensions Euro 11.2 billion or 8% of GDP;
- Health 6.2 billion euros--4, 43% of GDP;
- Education and Research, 4, 4 billion euros. -3, 14% of GDP;
- Social insurance and social assistance-16, 5 billion euros -11, 78%.

Share of spending will be 46 billion euros. Euros, or 32.85% of GDP and total expenditure budget will be 49 billion difference being covered by the budget deficit.

The share of social expenditure in total budget will be:

- Social security and social assistance-33, 67%
- Expenses for health-12, 65%
- Education and research-8, 97%.

Calculated per capita (population about 20 million people), a GDP of 7,000 / inhabitant. the following data:

- Social security and social assistance-825 / person;
- Expenses for health-310 / person;
- Education and research-220 / person

The three groups of expenses totaling 1355 euros and will represent 19.35% of GDP / capita.

### **Conclusion, proposals, recommendation**

1. The paper analyzed the main trends in the evolution of social expenses in the period after 2008 the education, given the economic crisis event in Romania.

2. Processing and interpretation of statistical data allowed us to notice that our country is among the poorest EU member countries:

- level-in terms of GDP / capita
- The share of social spending in total GDP and / capita;
- share of social expenses in total budget expenses;
- Average income / household and / person

3. The study reveals the slow pace of poverty reduction in the gap between the level of welfare in Romania and the EU average.

# APPROACH OF RDI SYSTEM IN EUROPEAN UNION IN THE LAST DECADE

**Nicolov F. Mirela**

*University of Oradea, Faculty of Economic Sciences, Oradea, Romania  
e-mail: nicolovmirela@gmail.com*

**Abstract:** *Present paper present an approach of the Research-Development and Innovation System (RDI) in Europe during the last decade. After a short introduction is presented the European Union formation. Research, development and innovation (RDI) has been studied and analyzed since 2001 by the European Innovation Scoreboard (EIS). Will be presented in the present paper a summary of all the materials from EIS 2001 till IUS 2011. Study concerning RDI system in Europe was done from innobarometers from 2001 till 2010. EIS2007 presents for the first time the European innovation leaders. EIS presents innovative performance of Member States based on annual statistical data collected from national statistical sources of each member country of the European Union through the Community Innovation Survey by using Document Analysis on Innovation Community. Were taken into account, after this short presentation, the relevant composite indicators for European Union for the last decade to analyze the Research-Development and Innovation System in Europe. IUS2011 distinguish between three main types of innovation indicators. The main input factors in the analysis of external innovation performance of firms covers 3 dimensions of innovation. These indicators, based on the IUS2011, contain as follows: Human Resources with the evolution of new doctorate graduates, population completed tertiary education, youth with upper secondary level education, Research Systems, Finance and Support. All of these indicators belongs to the category of Enablers. Another indicators studied in the present paper are Firm activities, Linkages & entrepreneurship Intellectual Assets. From the category of Outputs there are Innovators and Economic effects. The composite indicators for EU Research Development and Innovation System were study for the period 2006-2011. Samples data were took from Pro Inno Europe database for simulations in August 2012.*

*The present study is part of Doctoral Grant "Implications for innovation, research and development role in the development of Romania's economic competitiveness", for the period 2010-2015 having Director: Prof. Dr. Alina Bădulescu in Oradea University, Faculty of Economic Sciences.*

**Keywords:** *Economic Development, Institutions and Growth, Europe, Institutional, Research Development and Innovation System*

**JEL classification:** *B25, O43, O52.*

## 1.Introduction

Present paper will make an analysis of the research development and innovation activities in European Union in the last decade.

Lisbon strategy introduced in 2000 was meant to transform by 2010 the European Union into "the most dynamic and competitive-based economy in the world" (Lisbon Strategy, 2000). A knowledge-based economy is a basic factor to strengthen the competitiveness of that economy. Economic growth is the increase of activities and their results in the national economy are closely linked to factors contributing to this

increase. Economic growth is interpreted as a positive development trend of macroeconomic outcomes expressed by the dynamics of macroeconomic activity results in real terms. Macroeconomic dynamics is correlated with demographic dynamics. Macroeconomic indicators are related to the total population. Economic growth is measured by the growth rate of GDP, the gross national product or national income per total and per capita. Economic growth is seen as a long-term process. It is the growth of potential output and potential output. Growth potential depends on existing resources and how they are made (Dachin&Popescu, 2009).

Economists and economic historians from Adam Smith raised the question of national economic growth. They wondered why some countries grow more rapidly? If these countries have the necessary capabilities for sustainable growth? Makes them more competitive in some countries than others and why some become richer than others? Attention has shifted from growth problems in the allocation of resources. The theory of firms comparative growth was first introduced in the works of Downk in 1958, Penrose in 1959 and Marris 1964. This was treated as a sub-branch of the industrial economy, which was a theoretical relationship between the firm and markets. Competitiveness is studied to understand whether the necessary capacity for sustainable growth in a competitive environment made internationally. Competitiveness is studying environment there are other countries, groups or individual companies. It is studied differentiated set of capabilities appropriate for each savings share. (Cantwell, 2006).

Present paper present an approach of the Research-Development and Innovation System (RDI) in Europe during the last decade. After a short introduction is presented the European Union formation. RDI has been studied and analyzed since 2001 by the European Innovation Scoreboard (EIS). Was presented in the present paper a summary of all the documents from EIS2001 till IUS2011. Study concerning RDI system in Europe was done from Innobarometers from 2001 till 2010. Were taken into account, after this short presentation, the relevant composite indicators for European Union for the last decade to analyze the Research-Development and Innovation System in Europe. IUS2011 distinguish between three main types of innovation indicators. The main input factors in the analysis of external innovation performance of firms covers 3 dimensions of innovation. These indicators, based on the IUS2011, contain as follows: Summary Innovation Index, Human Resources, Research Systems, Finance and Support, Firms investments, Linkages&entrepreneurship, Intellectual Assets, Innovators, Innovators, Economic effects for European Union (Source: <http://www.proinno-europe.eu/metrics>).The composite indicators for EU Research Development and Innovation System were study for the period 2006-2011.

## **2.A short aproach of RDI system in EU during EU formation**

European Union (EU) is an economic and political union consisting of 27 member states which are located primarily in Europe. In 1951 was founded the European Coal and Steel Community (ECSC). In 1958 was established the European Economic Community (EEC). In 1957 EU6 is formed, the first form of existence of the EU.

EU6 was formed in 1957 from the following countries: Belgium, France, West Germany, Italy, Luxembourg, Netherlands. When EU6 was created in 1957, had a total population of 169,106,736 inhabitants, comprised an area of 1,299,536 km<sup>2</sup>.UE6 have a GDP of \$ 1.123317 trillion and a GDP/capita of \$ 6,643. In

1973 EU9 was formed with Denmark, Ireland, UK in addition to EU6. EU9 thus formed, which has a population of 256,762,106 inhabitants, an area of 1,657,723 km<sup>2</sup>, a GDP of U.S. \$ 3.148472 trillion, or a GDP / capita of \$ 12,262. In 1981 Greece joins the EU, thus forming the EU10. Population grew by 3.72% and reached 271,472,541 people. Area increased by 7.96% from 1973, to EU9. Even if the total GDP of the newly formed EU10, increased by 2.34% to 3.781111 trillion \$ GDP/capita fell by 1.33%. In 1986 Portugal and Spain joined the EU and they make the EU12. The two countries have led to an increase in GDP of the EU to 11.29%. GDP/capita decreases by 5.51% to the value of \$ 14,468 / capita. Population grew by 17.53% and EU12 area increased by 33.37% to 2,386,841 km<sup>2</sup>. In 1995 to the EU12 joins Austria, Finland and Sweden, forming EU15. GDP per capita increased by 0.2%. EU15 population increases by 6.28%, the area increases by 34.95% and EU15 GDP increased by 6.5%. In 2004 another 10 countries join the EU15 and formed EU25. These are: Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovakia, and Slovenia. These 10 countries contribute to population growth by 19.5%, thus EU25 population reached 456,504,305 inhabitants. Surface increases by 17.97% and becomes 4,104,844 km<sup>2</sup>. EU GDP increases only 8.88% and reached \$ 8,396,994,000,000 of, but GDP per capita decreases by 8.94%, making him \$ 18,394 /capita. In 2007 Romania and Bulgaria join the EU and thus form the EU27. These two countries contribute 2.04% to EU GDP in 2007 which became worth \$ 12,436.80 billion and GDP per capita decreases by 4.03% and becoming in 2007, \$ 25,160.59 / capita. EU area increased by 6.48% in the two countries, reaching 494,296,878 inhabitants and the area is 4,454,237 km<sup>2</sup> and in EU27 is increasing to 8.51%. In 2011, the EU27 has a population of 502,486,499 inhabitants and EU GDP of \$ 15,788 billion and a GDP/capita of \$ 31,548.

(Source: <http://epp.eurostat.ec.europa.eu>)

Research, development and innovation (RDI) has been studied and analyzed in the present paper since 2001 by the European Innovation Scoreboard (EIS). EIS2007 presents for the first time that EU innovation leaders. EIS presents innovative performance of Member States based on annual statistical data collected from national statistical sources of each member country of the European Union through the Community Innovation Survey (Document Analysis on Innovation Community). European Innovation Scoreboard (EIS) is a document that contains information about: performance of Research Development and Innovation (RDI) in Europe. I took and studied every document since EIS2001 to IUS2011 respectively Inobarometers from 2000 to 2010. Next I will present a brief summary of the 22 official documents downloaded from the official website of the EU: <http://www.proinno-europe.eu/metrics>.

EIS2001 is the explicit answer of European Council meeting in Lisbon, establishing that the European economy have to be a dynamic, knowledge-based, social cohesion respectively. It was established that the RDI European area naem to be ERA (European Research Area). Statistical analyzes are made here for 17 indicators in 4 areas, such as human resources, knowledge creation, transmission and application of new knowledge, financial innovations and marketing results. Analyses are performed for 1999 and 2000. In the 2001 report states that leaders of innovation in Europe are Finland, Sweden, Denmark. These countries have enormous potential for RDI. All member countries improve their innovation performance. UK achieved the fastest way. Just manages of Denmark, Finland, Greece, Luxembourg and Spain, which are now entering countries in the catching-

up category. Many indicators regarding RDI in Europe are heavily influenced by public policies and strong investment in RDI or in achieving tertiary education especially after 1996.

Innobarometer 2001 examines the experiences and priorities of European managers on innovation activity. According to European managers, innovation is widespread, but it is a slow development. It appreciates the importance of innovation in most businesses. Adequate human resources, active contacts with customers and suppliers, and sharing knowledge with other innovative companies are considered important elements of innovation. However, tax incentives for innovation are considered insufficient in most EU countries. On the other hand, most of the directors claim that customers have a favorable attitude towards innovation. German customers are regarded as being particularly exposed to innovative products.

EIS2002 complete a survey of a new field of innovation, biotechnology and introduce the methodology for reporting the status of innovation in Europe in 2002.

Innobarometer 2002 examines European companies, which slowly but continuously strengthens their innovative activities between 2001 and 2002. Skilled workforce with the knowledge and skills necessary for a strong performance in innovation is regarded as essential in this context. Innovative market access are considered too. Another trend is observed in the period under investigation is that more and more companies took part in the increasingly public debate on innovation. Is highlighted the importance of cooperation between enterprises.

EIS2003 analyzes RDI achieved in the EU in 2003. Technical data indicate important economic issues such as: definitions of economic indicators that characterize the European Innovation at a time, analyze the performances. The results presented in the EIS documents include current data and trends, determining what innovation leaders, weaknesses and strengths of each country component of the EU. Analyses were performed for regional development, respectively for 173 regions from 13 Member States in 2003. Were studied on this occasion 9 structural indicators and 14 indicators of socio-cultural and institutional background specifying the conditions for innovation activities in each EU Member State. Was done on this occasion description of the methodology for calculating the summary innovation index SII (Summary Innovation Index) for each country.

Innobarometer 2003 reveal that the number of EU companies that have engaged in innovative activities increased from 2002 to 2003. An important factor is the consumers that encourages companies to innovate. Generators of research and development are the engines of innovation. Managers see globalization as an opportunity to innovate and are optimistic about the benefits of innovative efforts. At the same time is seen favorably European dimension of innovation issues such as the community patents.

EIS 2004 contains information about the candidate and who tend to join the EU, their Performance for RDI -business activities. EIS2004 includes a database with information on each economic indicator which characterizes RDI. This information is presented for each country component of the EU. This information presents the ways of achieving RDI, diversity, innovation feature of market knowledge flow, investments in RDI, innovation in governance respectively. Indicators study covers the period 1993-2004. Countries for which was made the analysis are: Austria, Belgium, Germany, Denmark, Greece, Spain, Finland, France, Ireland, Italy, Luxembourg, Netherlands, Portugal, Sweden, UK, EU15, Cyprus, Czech Republic, Estonia,

Hungary, Lithuania, Latvia, Malta, Poland, Slovenia, Slovakia, EU25, Bulgaria, Romania, Turkey, Iceland, Norway, USA and Japan.

Innobarometer 2004 seeks public support measures for innovation programs from a business perspective. This analysis includes 25 Member States. Analysis is performed for 4,500 innovative companies with a number between 20 and 500 employees. Through Innobarometer 2004 is the innovation performance of Member States and associated countries. One third of EU's innovative companies use at least one form of public support for their innovation activities. However, few companies use public support for innovation, for which they are eligible, which shows that further improvement can be achieved in terms of coverage of public initiatives. It was found that the Cypriot and Austrian firms are most active. Companies from new member states use less public support for innovation.

2005 EIS presents results of RDI activities and reporting methodology used in this year. This is how to assess and compare the innovation performance of EU countries and USA. There are also studies of the weaknesses and strengths of innovation results and economic performance of the EU Member components.

Innobarometer 2005 analyzes how people are ready for innovation in 2005. It is analyzed here how europeans define innovative products and services and the extent to which people are drawn these. This information was used to evaluate the overall innovation. It appears that Malta and Slovakia are Member States with the highest proportion of citizens pro-innovation. Many other countries are in the same situation. Citizens of Poland and Latvia are not prepared to accept the innovations. A study was conducted where three from five citizens of these countries are classified as "anti-innovation" or "reluctant". Peoples "anti-innovation" are in Greece, Cyprus, Portugal, Bulgaria. Most EU citizens more innovation associated with creating new products or services, improve existing ones. The vast majority of European citizens said that they feel attracted to innovative products or services.

EIS 2006 includes innovation indicators. Trends analysis is performed here for innovation in EU25 Member States plus the two new Member States: Bulgaria and Romania, and Croatia, Turkey, Iceland, Norway, Switzerland, USA and Japan. Corresponding Annex of EIS2006 contains tables with definitions and datas for each country. EIS2006 report and its annexes are accompanied by thematic papers and corresponding indicators database. In EIS2006 there is a comparative study between EU, USA and Japan, countries where RDI has important results.

Innobarometer 2006 presents descriptive information on the concepts of membership in a particular cluster and cluster impact on the economic competitiveness of Europe. Study finds that corporate managers are generally aware of the relatively new concept of clusters of companies, especially in the old Member States. It was found that EU action is placed in a cluster consisting of at least 4 companies with at least 20 employees. They are characterized by close cooperation with other local businesses and close links with local business infrastructure. The highest density of clusters is in UK, Ireland and Latvia. The benefits of belonging to a cluster are in the category of human resources, entrepreneurship and partnership development. Three quarters of business leaders strategic component clusters in the EU considers strong competition and competitiveness generator, which ensures the success of clusters. Companies operating in the cluster are more innovative. Public authorities has an important role in supporting clusters (Source: <http://www.proinno-europe.eu/metrics>)

EIS 2007 include RDI indicators and trend analysis of the EU27 Member States. Data presented here are for EU27, Croatia, Turkey, Iceland, Norway, Switzerland, Japan, USA, Australia, Canada and Israel. For the first time were included in these types of analyzes Australia, Canada and Israel. Is made here a comparison between EU member states of these countries. This year EIS analyzes the RDI services, factors influencing innovation performance and efficiency. EIS2007 reflect analyzes of seven years of experience in benchmarking countries of RDI.

Innobarometer 2007 refer to the transfer of innovation. Here is how companies innovate, role-based innovations RDI innovations made without research and development process. Innovation can be outsourced or transferred to other companies or organizations. In a number of Member States of the EU and Norway and Switzerland intensive industries are selected to be involved in innovation. It requires that innovation process is involved in about nine of ten companies. In Finland, Hungary or Sweden every euro is spent on RDI. Innovation leads to increased turnover. Innovative companies are successful. The figures do not indicate that innovative companies that have a turnover which has been growing in recent years. Innovation is more characteristic for larger firms.

EIS 2008 provides a comparative assessment of the innovation performance of EU Member States, in accordance with the Lisbon Strategy. Revised methodology for EIS2008 is compared to 2007. The focus is increasingly on services, the non-technological innovation outcomes. Analyze temporal trends based on changes in the absolute values of the indicators for five years. Previous approach to innovation trends were performed by measurements made in relation to the EU average.

In 2008 it was realized no innobarometer.

EIS 2009 monitor the implementation of the "Europe 2020" strategy. The EU is seen as an Innovation Union. Provides a comparative assessment of the innovation performance of the EU27 Member States. Are presented the strengths and weaknesses in RDI systems. Studying innovation in the European Union can be seen next event at European level thus created groups of countries were was identified by computational methods of group clustering such as Ward method, the method connection between groups, the method links inside groups, nearest neighbor, farthest neighbor, median and central clustering methods (Source: <http://www.proinno-europe.eu/metrics>).

Innobarometer 2009 made a profile of innovative companies which are coming from innovative intensive sectors, with at least 20 employees, based on innovation as the primary source of income. Hungary has the most companies which have innovation. In Cyprus and Finland there are many companies that are dependent on innovation as the main source of income. Were introduced in 2006-2008, innovations for products, services, processes, marketing strategies, organizational changes. Companies from Slovenia, Finland, Switzerland and Sweden have introduced at least one type of innovation. Hungary and Bulgaria were at the lower limit on the introduction of innovations. Expenditure done for machinery, equipment or software was the most common form of innovative investments. Most companies had a stable budget for innovation or stagnation due to inflation from 2006, 2008 and 2009. Direct effects of the economic crisis in this period did not result in any changes in RDI expenditures. Production companies of high-tech increased RD expenses during the period of growth stagnation. A large number of companies at the border of UK, Spain, Poland supported innovation activities, but not France, Germany and Italy. Slovenia, Cyprus, Ireland and Luxembourg had intense international activities to support

innovation. Businesses operating across borders within the EU have supported innovation in the EU, especially in high-tech manufacturing sector, which most demanding customers. Companies in this category have received income from sales of innovative products and services. Public policies can influence innovation activities too.

IUS 2010 analyzes the innovation in EU27. The new tool is designed to help monitoring and implementing the "Europe 2020" strategy which provides innovative performance EU27 Member States and the strengths and weaknesses of RDI systems. IUS2010 conclusions on relationship between performances of RDI countries competitiveness are: 1. Innovation Leaders: Denmark, Finland, Germany, Sweden showing performance significantly above that of the EU27; 2. Innovation Followers: Austria, Belgium, Cyprus, Estonia, France, Ireland, Luxembourg, the Netherlands, Slovenia and the UK have a performance close to that of the EU27; 3. Moderate innovators are: Czech Republic, Greece, Hungary, Italy, Malta, Poland, Portugal, Slovakia and Spain is below that of the EU27; 4. Modest Innovators are: Bulgaria, Latvia, Lithuania and Romania for the innovation performance is well below that of the EU27. Bulgaria, Estonia, Malta, Romania, Portugal and Slovenia are leading growth, with an average annual growth rate of more than 5%. (Source: <http://www.proinno-europe.eu/metrics>)

Innobarometer 2010 found main effects of innovations in public administration. At EU level, two-thirds of public administration introduced a new or significantly improved service in the last 3 years. Innovation in services increased probability proportional to size institutions both public and private ones, which were observed in the leading innovators in public sector organizations. Process leading innovators were usually large organizations of national or central type. The most important engine for innovation in the public sector was the introduction of laws and regulations. Major sources of innovation is based on ideas from staff, management ideas, ideas from customers or users. Were introduced innovative practices from the bottom up. Was mentioned managerial support for testing ideas for the process error. (Source: <http://www.proinno-europe.eu/metrics>)

IUS 2011 include indicators of innovation and trend analysis for the EU27 Member States as well as Croatia, Iceland, the former Yugoslav Republic of Macedonia, Norway, Serbia, Switzerland and Turkey. This includes comparisons between EU27 and other 10 countries worldwide. The main data analysis of external innovation performance of firms covers 3 dimensions of innovation as follows: human resources, open, excellent and attractive research systems, and finance and support. Business activities refer to efforts made at the company's innovation, innovation grouped into three dimensions: investment firms, linkages and entrepreneurship and intellectual assets. The results refer to effects on innovation activities of firms in innovation, which are the two dimensions: innovators and economic effects (Source: <http://www.proinno-europe.eu/metrics>).

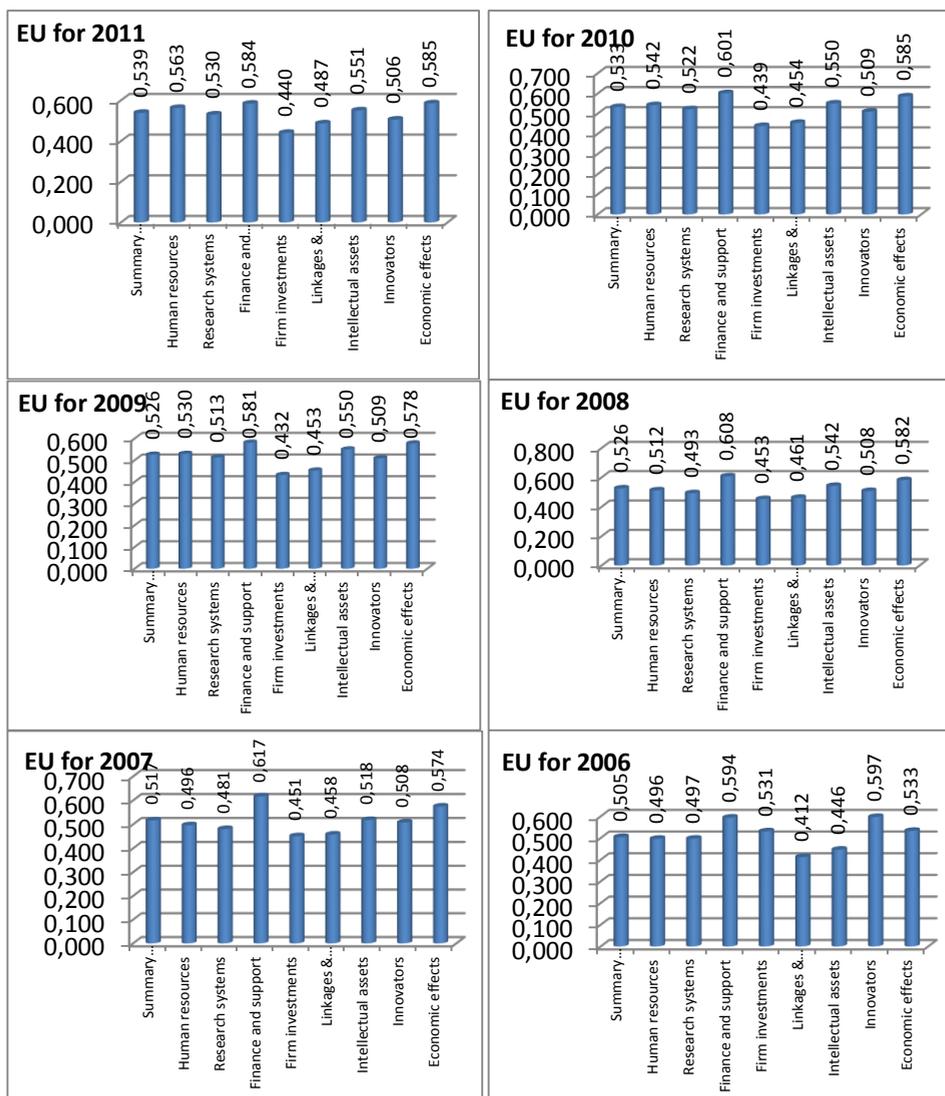

### **3. Analysis of relevant indicators for European RDI systems**

IUS2011 distinguish between three main types of innovation indicators. The main input factors in the analysis of external innovation performance of firms covers 3 dimensions of innovation.

Figure 1 contain composite indicators for EU for the period 2006-2011. These indicators, based on the IUS2011, contain as follows: Summary Innovation Index, Human Resources, Research Systems, Finance and Support, Firms investments,

Linkages&entrepreneurship, Intellectual Assets, Innovators, Innovators, Economic effects for EU (Source: <http://www.proinno-europe.eu/metrics>).

Summary Innovation Index (SII) gives an overview for the moment of aggregate national innovation performance. This is an indicator which has the highest value in 2011 respectively 0.539 and the lowest value in 2006 as 0.505. The SII is calculated using the most recent statistics from EUROSTAT and other internationally recognised sources as available at the time of analysis, as in IUS2011. As a consequence the SII does not capture the most recent changes in innovation performances, or the impacts of policies introduced in recent years which may take some time to impact on innovation performance. Human Resources present the evolution of new doctorate graduates, population completed tertiary education, youth with upper secondary level education. This indicator has the highest value in 2011 respectively 0.563 and the lowest value is 0.496 obtained in 2006 and 2007. Research Systems present the evolution of international scientific co-publications, scientific publications among top 10% most cited, non-eu doctorate students. This indicator has the highest value in 0.530 in 2011 and the lowest 0.481 registered in 2007. Finance and Support present the evolution of public RDI expenditure and venture capital. This indicator vary between 0.617 in 2007 and 0.581 in 2009. All of these indicators belongs to the category of Enablers. To the Firm activities belongs: Firms investments with evolution of RDI Business expenditure and Non-RDI expenditures. This indicator vary between the lowest value of 0.440 registered in 2011 and 0.531 which is the highest value registered in 2006. Linkages & entrepreneurship present the evolution of SMEs innovating in-house, innovative SMEs collaborating with others, public-private co-publications. This indicator vary between 0.412 in 2006 and 0.487 in 2011. In the category of Intellectual Assets is presented the evolution of PCT patent applications, PCT patent applications in societal challenges, Community trademarks, Community designs. This indicator vary between 0.551 registered in 2011 and 0.446 in 2006. From the category of Outputs there are Innovators with evolution of SMEs introducing product or process innovations, SMEs introducing marketing/organisational innovations and Economic effects with evolution of Employment in knowledge-intensive activities, Medium and high-tech product exports, Knowledge-intensive services exports, Sales of new to market and new to firm innovations, Licence and patent revenues from abroad. Innovators is an indicator which vary between 0.597 in 2006 and 0.506 in 2011. Economic effects is an indicator which vary between 0.533 in 2006 and 0.585 in 2011.

**Figure 1:** Composite indicators for EU during period 2006-2011. (source: <http://www.proinno-europe.eu/innometrics/page/innovation-union-scoreboard-2011>).

#### 4.CONCLUSIONS

The relevant composite indicators analysis for the European Union RDI system covers the next dimensions of innovation as follows: human resources, open, excellent and attractive research systems, finance and support respectively. Entities that carry out RDI activities refers to efforts made for innovation at the firm level, but also at public level too. They are grouped into 3 dimensions of innovation: investment firms, linkages and entrepreneurship and intellectual assets. The results of such analysis concerns the effects on innovation activities, which are: innovators and economic effects. For this reason all innovation leaders should have high values

for RDI expenditure for the categories of business, innovation, human resources, finance and support and firm investment. All innovation leaders should have high values for publications made in public-private partnerships, publications made at 1 million people, suggesting good links between fundamental science and business. All top European innovators must excel in marketing technological knowledge, which can be seen from their performance on foreign income from licenses and patents. Good overall performance of innovation leaders should reflect a balanced national research and innovation. Effects are improving business innovation innovative public administrations. They improved working conditions and employee satisfaction. Human resources can support innovation. Future trends are increasing the number of public sector organizations in the EU27 introducing innovations.

This analysis is done in correlation with all the RDI documents from EIS2001 to IUS2011 and Innobarometers 2001 to 2010.

The main findings from the present study are: that Human Resources and Research Systems are increasing in the last decade. Finance and Support present the evolution of public RDI expenditure and venture capital is an indicator which has the highest values in 2007. The indicator Firm shows an increase in the last decade. Intellectual Assets which present the evolution of PCT patent applications, PCT patent applications in societal challenges, Community trademarks, Community designs is an indicator which show an decrease in the last decade. Innovators shows an decrease in the last decade and Economic effects shows an decreasing variation in the last decade.

**Abstract:** *The absorption of EU funds for Romania is a necessity in the nowadays context. The slow pace of absorption of these structural funds earmarked for Romania as EU member state is a deficiency with negative effects on the economic and social development of our country. Their low absorption shows deficiencies in their coordination and implementation at central level and also at the level of beneficiaries. Their coordinative authorities, in particular the Managing Authority of Structural Instruments, together with its subordinated institutions presents deficiencies in their coordination and implementation as having negative effects on their absorption. The main weaknesses identified on national level mainly consist in the lack of specialized personnel, in excessive bureaucracy and a mismatch of national legislation with the European one. The lack of transparency and change is specific to these structural funds, representing deficiencies that lead to beneficiaries' discouragement to implement projects financed from structural funds. In the Sectoral Operational Programme, the Human Resources Development Program is a leader in the rate of absorption but it also has the largest number of problems and deficiencies in implementation. Due to the deficiencies identified by the auditing European Commission of the Sectoral Operational Programme Human Resources Development, payments were suspended for a period of four months. Following this situation, it was necessary to implement the necessary corrective measures at the level of POSDRU, leading to its release. Taking action and removing the deficiencies at the POSDRU level, and also at the level of other operational programs, it is a necessity and a priority to increase the absorption of these funds. The main measures that need to be taken mainly consist of training the personnel involved in the management of these funds, reimbursements release funds to the final beneficiaries, creating a more transparent system of evaluation of proposals and a better correlation of national legislation with the European one. The challenge is to implement measures identified and increase the absorption of structural funds until the end of their deployment.*

**Keywords:** *absorption of structural and cohesion funds, deficiencies in the implementation of structural and cohesion funds, measures to improve the management of structural instruments.*

**JEL classification:** R11, R58

## Introduction

Romania currently receives grants allocated by the European Union through the Structural Instruments, namely the Structural and Cohesion Funds.

Although the present economic situation in Romania is poor, being in a continuous economic crisis and these funds represent an opportunity for growth and survival

and survival for the organizations regardless of their form and type, the absorption level of these grants is quite a low one, of 13.05% at 31 March 2013.

The low level of absorption of these funds indicates their ineffective implementation at the national level. This implementation is inefficient due to the lack of experience of Romania in their implementation which causes problems in their implementation both at the national level and at the level of final beneficiaries.

The identification of key issues and adoption of measures for their removal is an essential condition for attracting these grants with positive effects on the national economy.

Given the fact that nowadays we are at the end of the implementation of these structural and cohesion funds, the overall rate of absorption is very low, we were supposed to have had the absorption rate around 60% interim payments from the European Union.

In order to determine the main issues that led to this low absorption rate, an overall and specific analysis is required for each program. Because the Sectoral Operational Programme Human Resources Development is one of the programs with an average absorption rate, an analysis identified the main difficulties in implementing this program at the macro - management authority level, which cause deficiencies and at micro level - final beneficiaries, is appropriate and necessary. According to the "State absorption of Structural and Cohesion Funds, on 31 March 2013, Operational Programme ", POSDRU has a 37.10% share of domestic payments to beneficiaries and 13.08% interim payments from the European Union to Romania from the initial allocated budget.

## **Content**

In order to determine the main weaknesses which led to such a low absorption rate, allocated grants by the POSDRU, an analysis is required at the level of direct beneficiaries of these projects and reports on their implementation and co-ordination is issued by the competent authorities at the EU.

The low degree of absorption is the main indicator that signals the existence of problems in the implementation of grant programs. The degree of absorption is determined by the capacity of absorption on both macro and micro level. The absorption capacity is given by the authority of a member state to spend financial resources from the structural funds in an effective way, targeting three areas:

- Macroeconomic absorption capacity, defined and measured in terms of GDP (limited to 4%);
- Financial absorption capacity, defined as the ability of co-financing programs and projects supported by the EU, to plan and guarantee these contributions in their multi-annual national budget and collect contributions from partners involved in various programs and projects;
- Administrative capacity, which is the ability and competence of central and local authorities to prepare adequate programs and projects in a timely manner, as well as ensuring the coordination with the partners involved, compliance with administrative and reporting requirements, funding and monitoring the implementation of programs and projects and also, avoidance of irregularities.

Given the definition of absorption capacity specified above, we can assume that it is mainly influenced by managerial and administrative capacities of co-financing. The relationship between the absorption capacity of structural funds and regional economic situation is at least a paradoxical practice demonstrating that the most

disadvantaged regions facing the greatest difficulties in absorbing these funds, although the need for financial support for the restructuring of the economy is paramount in these regions. The main explanation for this phenomenon is given by two factors: on the one hand, the difficulties faced by regional authorities due to lack of experience and skill, followed by slow bureaucratic procedures and the nature of EU decision-making procedures in circumstances where sequential programming central and regional level in particular are not quite clear. Thus, issues of absorptive capacity factors depend heavily on EU institutional structures and national markets. To reflect the main deficiencies encountered by beneficiaries of grant projects allocated within the Sectoral Operational Programme it was monitored the implementation of a number of 70 projects under various types of organizations, public institutions of education and higher education, companies as Ltd and Plc, as well as NGOs.

In this approach were performed interviews with project managers and legal representatives of the organizations. The interviews were aimed at highlighting the difficulties they faced in specific stages of project management method. For these specific steps were identified the main weaknesses: identification and project submission, project implementation and their evaluation stage.

Regarding the identification and submission Phase of a POSDRU project, beneficiaries consider this step as a cumbersome and a difficult one. Aspects specified by beneficiaries behind this assertion are held by many changes of the Guide for Applicants - General and Specific Conditions based on the Corrigendum modifying the initial conditions and triggering a restructuring and in some cases abandonment of the project idea. Most common changes in a request for proposals are usually on issues such as delaying the deadline for submission of applications, changing the types of indicators, of eligibility of activities, and even the applicant's eligibility. The best example is the request for proposals for projects 89 and 88, in 2009, when submitting projects were brought forward by extending according to Corrigendum 6 and the project application no. 109 in 2010, when in a press release dated 25.09.2010 (Friday) at 16:00 the call announced the closure on 27.09.2010. All these changes lead to de-motivation potential beneficiaries and low absorption of these grants, denoting a poorly coordinating management of the institutions.

Another negative aspect mentioned by beneficiaries for the accessing process is the evaluation of applications, namely the lack of transparency in AMPOSDRU, and the lengthy process of evaluation of projects, sometimes for over a year until the contract date deposit. A very eloquent situation regarding the lack of transparency in project proposals assessment is the sending of the assessment documents a year and a half after the start of the project with specific modifications of project activities thus jeopardizing the project. Communication with beneficiaries and respect of the principle of transparency in managing and use of public funds imposed by the European Union is violated from the beginning of the process of allocating until the final beneficiaries.

If accessing and contracting these grant projects through the Structural Instruments is a cumbersome process that denotes lack of experience of the staff involved in their programming and evaluation of project applications, which is a percentage of about 20% of the method of Project Management implementation, then the phase of implementing and reporting / evaluation of these projects cannot be a better one. The implementation of projects financed by the Structural Instruments requires rigorous and thorough enforcement of legislation. Thus these types of projects are

subject to national legislation and especially the legislation imposed by the EU in this area. One of the impediments in the implementation of such projects is the lack of legislative reform and regulatory changes especially in the financial and procurement area. An example of legislative amendments in the financial area is considered to be the Order of Eligible Expenditures related to the Sectoral Operational Programme Human Resources Development that was modified in the process of project implementation the last version was published in August 2010. Under this Order, each beneficiary of grant project funded through this program was forced to revise and re-plan the project budget. The emergence of new instructions through the projects with different requirements and new regulations do nothing to hinder the implementation of projects and adverse effects. The most obvious and recent example is the changing of format of HR Activity Report through Instruction 62, which originally required the restoration of retroactive human resources activity reports, i.e. forcing the beneficiaries of projects to substituted documents, but due to the reactions of the beneficiaries, this instruction has been revised. Retroactivity principle of law, especially the administrative nature of the documents, that is the instructions in this programme, is violated by the Management Authority that has issued an Instruction that applies retroactively. This instruction was applied by the Management Authority and caused significant ineligible costs for the final beneficiaries of projects financed by POSDRU. Therefore, the main problem faced by beneficiaries in this stage is not failing of project activities, but coping with the changes imposed by the Management Authority and to predict the occurrence of possible administrative regulations of the program due to national legislation instability.

Excessive bureaucracy imposed by the Management Authorities, constantly issuing of administrative normative documents with administrative character, determines the beneficiaries to depart from the actual implementation of their project objectives and focus especially on the administrative side of it, in order to recover costs for carrying forward the project.

Another barrier in the implementation of projects financed by POSDRU is to ensure financial liquidity to implement projects due to delays in the payment of pre-financing and reimbursement requests on projects. Thus for some projects, beneficiaries had to wait up to 6 months to start the pre-financing payment for project activities and in some cases a period of one year until the transfer of the amount of the refund request, although the contract stipulates funding for a period of up to 45 days. These delays in the payment of pre-financing and reimbursement requests lead to the dissolution of the financing contract due to the inability of beneficiaries to advance the amounts of money for the activities covered in the applications. The dissolution of contracts of funding has an effect on the absorption of structural funds.

In many cases the beneficiaries of these projects, as due to delays in payment of claims for reimbursement, reached to the case of them being unable to conduct project activities and even basic activities of beneficiaries due to lack of liquidity and the allotment of own revenues in POSRDRU project implementation without it being recovered in due time estimated by the beneficiaries. Based on an analysis of annual accounts of the beneficiaries monitored, it could be seen that these balances for 2010, 2011 and 2012 were in the red, the main reason being that of leading amounts in implementation of POSDRU projects, and their impossibility of being taken back from the Management Authority. Some beneficiaries of these projects went for bank loans for the implementation of POSDRU projects, to which are

charged and paid interest, at the very best, many beneficiaries being in the impossibility of paying the financial loan payment. Small size beneficiaries are in even in bankruptcy.

The evaluation - reporting phase of projects at the level of beneficiaries and their transmission to the bodies facilitated to assess, represents a difficult step due to their failure in assessment. Whatever the type of beneficiary and the type of reporting, either final or intermediary, this process is one of the poorest and most problematic. The main failure of this stage encountered by final beneficiaries is the volume of documents submitted and the changes imposed by the standard document Management Authority.

Therefore, the problems identified at the level of beneficiaries are mainly caused by the Managing Authority of the program. These problems are mainly caused by lack of experience in implementing these programmes and the inability of forecasting and planning of programmes according to the method of project management.

Even the EU, after an audit, identified many legal issues improperly implemented and many unapplied principles applicable to these grants resulted in blocking these programme regarding payments by the European Commission to Romania for 6 months in 2012.

The main problems identified by the EU representatives in implementation Reports, Priority Action Plan and the Report of the Audit Commission were mainly regarding delays in the launch stages required for proposals and terms of submitting too short, lack of transparency in formulating guidelines and guides applicant unclear, too much time in evaluation, submission and evaluation of reimbursement claims, deficiencies in respect to specific enforcement of the law, as well as projects control and monitoring. The most important and most significant part is, I think, that caused the previous problems and observed by the staff of the EU Commission is the staff training in these bodies and its deficiency in this structure.

Problems identified among beneficiaries of POSDRU projects by their monitoring in these projects are the exact identified issues by representatives of the European Union.

Previous deficiencies are largely caused by the institutional system also. Constant changes in the institutional system due to constant changes of these leaders have caused imbalances and slowing the implementation of POSDRU. Adopting a model of institutional organization practiced by countries with experience in implementing this type of program was necessary.

The implementation of POSDRU projects created the need for organizational structures to change the beneficiaries in order to achieve an efficient and effective implementation. The beneficiaries of significant size were established specific departments to manage and monitor the implementation of these projects and reducing the risk of irregularities, while providing support to project managers regarding their main difficulties that had to face in implementing these projects.

The lack of experience in Projects Management in Romania in institutions is a weak negative effect. This lack of experience and knowledge of project management principles can be seen on the staff involved in the coordination, implementation and monitoring of grant financing instruments.

Poor planning of the Structural Funds has negative effects, continuous re-planning and continuous changes lead to an inefficient control. Most of the problems identified in accessing, monitoring, control and reporting related to project planning. Legislative and political changes in the country have negative effects, political

changes and replacing leaders of the Management Authorities, Intermediate bodies, and lead to changes in the implementation of projects that are not good for the beneficiaries of such projects among them creating the confusion..

### **In conclusion**

In order to improve project implementation as the main beneficiaries may be adopted and whose effects are immediate and consist of monitoring visits on the spot and making recommendations based on achieving a correlation between all project specific documents.

To avoid irregularities in the following requests for proposals and consider their implementation efficiency necessary for the Management Authority of the programme, to make training sessions for project managers within the beneficiary institutions. Providing beneficiaries with information packages and information on final instructions applicable to this program is the essential condition.

An effective measure to streamline the process of evaluating applications for reimbursement and the creation of a more effective control of ongoing projects is the assignation of a monitor and evaluator for a project from its inception to its end. The number of projects a person can achieve to be made according to that person's competences, skills and ability. Implementation of this measure found to be absolutely necessary because it would avoid the existing times now due to constant changes in reimbursement claims assessors for a single project. The advantages of this measure are that the project is much better known by the monitors, the answers given by these beneficiaries are more grounded and clear, there is a better correlation between the indicators and results achieved target group expenses. By adopting this measure, I consider that the time of evaluation of requests for reimbursement and their payments would be significantly reduced thus removing major failures by the lack of liquidity for the project to the beneficiaries.

Failures shown represent the most significant aspects which decrease the level absorption. In addition to these disturbances there are external factors affecting the implementation of these programs and attracting grants from the European Union under the Operational Programme Human Resources Development.

Therefore, Romania's inability to adapt to EU requirements, the proper organization of a project grants implementation, especially regarding the Human Resources Development Operational Programme, by establishing clear, simple rules, and in line with the EU's, lead to the de-motivation of beneficiaries to access such projects, in some cases even lead to bankruptcy of beneficiaries of such projects.

A correlation of the legal system, its strict application and specialization of human resources within the Management Authority of POSDRU, is a strict and essential condition to use the opportunity of economic development of our country by financial support allocated by the European Union.

The need for an appropriate project management is revealed from all the issues raised in view of the economic and social development of the opportunities offered by the European Union.

Identification of examples of good practice in accessing and implementing Structural Instruments from other European Union countries is an opportunity to increase the absorption of Structural Instruments.

The effectiveness and efficiency of this programme can be captured only by the making of a study on the correlation between the effects post-implementation and the implementation of this program at the macroeconomic level.

# VIEWS OF ROMANIAN ECONOMISTS ON THE CYCLICAL FLUCTUATIONS IN ECONOMY

**Pitorac Ruxandra Ioana**

*Department of Economics and Economic Modeling, Faculty of Economics and Business Administration, West University of Timisoara, Romania  
ruxandrapitorac@gmail.com*

**Abstract:** *As part of a larger work, the objective of this article is to identify the Romanian economists concerned with the study of economic crisis and cyclical fluctuations and to critically and theoretically review the Romanian literature on this subject. The research is a qualitative one and it is based upon the studying of the specialized intern literature, the tools for this research were analysis and synthesis. The study of the Romanian economic thought, concerned with explaining the causes of cyclical fluctuations, has a special importance in understanding the economic system, in general, and in taking the right measures in mitigating the fluctuations and in economic recovery after a crisis period, in particular. The starting point of the theories regarding the cyclical fluctuations in Romania is 1929, when the economic crisis broke out, with serious effects on the development of Romania. An extensive literature has been written on the economic crisis of 1929-1933, in which Romanian economists exposed their views on the causes that generated it and the solutions to get out of that state. The same thing happened during the crisis in 2008-2010. When its effects were felt in Romania, the national economists tried to explain the causes of economic crisis, as well as finding ways of recovery for the Romanian economy. The research reveals the fact that all the analyzed theories, regardless of the historical period, considered the causes of cyclical fluctuation, in general, and the causes of economic crises, in particular, as being endogenous. (technical progress, investment, consumption, production variation, overcapitalization) The presentation of the economists who were concerned by this research is not exhaustive but selective and the most representative were elected to the matter under discussion, based upon the impact of their research on the economic fluctuation theories. It is necessary to take into account the nature of the economic and social era of the historical period in which they were made, and the historical moment not only puts its mark on the theoretical generalizations but also determines their limits.*

**Keywords:** *cyclical fluctuations, economic theories, crisis, Romanian economists*

**JEL classification:** *E32*

## **1. Introduction**

The theories of Romanian economists on cyclical fluctuations and economic crises emerged in the period 1929-1933 when the great economic recession broke out, with serious effects on the Romanian economy.

The views on this crisis were divided: Paul Horia Suciuc argued that it was a crisis of the liberal capitalist system, Mihail Manoilescu saw it as a transformation crisis of the whole system of production and exchange of humankind, Victor Slăvescu and D.

Rottman considered it a repercussion crisis with monetary reflexes and the Marxist theorists argued that it was a crisis of overproduction caused by the fundamental contradiction of the capitalism and was underpinned by a global crisis. (Tudosia, 1992: 225)

Romania faced an agrarian problem during that period, and a long agrarian crisis afterwards, which was international in nature, and the industrial cyclical crisis had dramatic impact on agriculture.

The explanation of the origin and nature of Romanian economic thought regarding economic crisis and cyclical fluctuation in the economy and their impact on the Romanian economy have a major importance in understanding the economic system and in taking the adequate measures to mitigate the fluctuation.

This paper represents a qualitative analysis of the theories regarding crisis and cyclical fluctuation in economy, which is based on the study of specialized intern literature, analysis and synthesis. The grouping of the selected economists was made after the impact which their work had on the economic fluctuations theories.

Among the Romanian economists who were concerned with the study of the economic crises and cyclical fluctuations in the economy we mention: Virgil Madgearu Gheorghe Badrus, Costin Murgescu, Tudorel Postolache, Emilian Dobrescu, Silviu Cerna, Liviu Voinea and Alex Berca. The presentation of the theories of the economists mentioned above will be made in the following.

## 2. Romanian Economists Concerned With the Study of Economic Crises and Cyclical Fluctuations in the Economy

The Romanian economist who best understood the crisis of 1929-1933 and sought out exit solutions not only nationally, where opportunities were limited, but also internationally, was *Virgil Madgearu*. He considered that the economic solidarity of agrarian countries and the reopening of the market of major industrial countries for agricultural products in Central and South Eastern Europe were the solution to exit from the economic crisis.

This meant giving up the most favored nation clause and the adoption of preferential tariffs, which satisfied the interests of Romania and all agrarian countries, but not of the American and West European circles. (Tudosia, 1992: 225)

Other proposed solutions to exit from the crisis were: the transition to the management of the economy by the state, the conversion of agricultural debts, lowering and expanding credits and contracting external loans.

Some of them have been put into practice, but the exit from the crisis has been difficult because the developed countries have transferred some of their difficulties to some less developed national economies, including Romania.

The economist *Tudorel Postolache* exhibited in several works his considerations on the theory of secular cycles ("*Ciclurile lungi și perspectivele economiei mondiale în viitorul sfert de secol*" (1971) and "*Ciclul secular și etapele capitalismului*" (1973)), namely that "the material basis of the secular cycle consists of the scientific research and technological innovation cycle in organic connection with the cycle of structural changes of the economy" (Postolache, 1981: 137)

He uses this theory to better understand the economic crises and developments in the economy of capitalist countries (which are cyclical, in long phases of 20-25 years, with alternating ascending and descending phases) and the world economy and announces "the influences of the secular cycle's phases and stage development on

the decennial cycle's development and phases in the capitalist economy and hypothesizes the existence of a secular cycle under socialism."(Postolache, 1981: 187-193)

Another economist interested in cyclical fluctuations was *George Badrus*, who believed that " the investment cycle should be reviewed and adjusted to the scientific and technical progress, taking into account the cumulative effects of this couple of cycles on the general cycle" (Badrus, 1988:189 ) and the essence of the revolutionary technological processes consisted in creating 'artificial intelligence'. This meant the crisis of the industry and industrialism, as a specific system of productive forces, as well as of the capitalist socio-political system, where it reached its height, and the start of a new great cycle in the history of humankind progress. (Vela, 1986: 144-146)

The slowdown in accumulation, economic growth and increased productivity in developed capitalist countries in the 70s and 80s, is due, in Badrus' opinion, to the "structural crises such as raw materials, energy and environmental shortages. The common denominator of these structural crises is that they have led to a huge mass of relatively additional capital in the form of accelerated obsolescence of production equipment and therefore to a lost capital. This mass of relatively more capital, appeared for the first time in the history, and created rare brakes and barriers to the historical process of capital accumulation, to which the capitalist process of reproduction cannot resist even in the descending phases of the industrial cycle." (Badrus, 1988: 143-144)

The economist believes that the various structural crises strongly influence the development of economic processes in different countries, but the main sources of the newly arisen phenomena in the cyclical course of reproduction are likely endogenous. "Although reproduction suffers the same repetitive phases (production, circulation, distribution, consumption), experiencing periods of expansion and contraction, yet the overall result is the increase in the society, wealth, the emergence of changes in the economic structures from one cycle to another." (Badrus, 1988: 171)

Given the increased interdependence of national economies and the fact that the global economic crisis, characterized by a high complexity, affected in one way or another all countries, one can advance the hypothesis that there is a more pronounced gradual inclusion of all national economies into a global cyclical fluctuation.

The economist *Costin Murgescu* believes that the economic crisis is an "expression of the historical development state of humankind and foremost of numerous and powerful contradictions that are interwoven into the global economy as a whole" (Murgescu, 1986: 45)

The global economic crisis encompasses a series of global crises (of the productive apparatus, energy, raw materials, food, monetary and financial, of the trading system, international technology transfer arrangements, environmental) strongly independent and affecting the fundamental cells of the global economy, widening the gap between them, hindering the economic flows and the mechanisms of international cooperation. (Badrus, 1988: 150)

Emilian Dobrescu is known mainly for developing the macromodel of Romanian economy and also for analyzing the economic cycles since the socialist period, considering that they "are not always negative phenomena imposed by the spontaneous course of the economy" (Dobrescu and Postolache, 1990).

He based the idea that not only capitalist economies but also the economies of the socialist countries know various forms of cyclicity in their development, linking this cyclicity to economic equilibrium forms. (Badrus, 1988:149) Thus, he gave new dimensions to his ideas by creating a typology of business cycles, a characterization of the optimal macrocycle and a mathematical formalization of its components in terms of existing correlations between the economic mechanism and the socialist reproduction.

A first approach addresses the dynamic equilibrium of the economy. This is based on the fact that, irrespective of the production function at a time, its performance will be affected by the restriction of certain factors (such as active population, physical capital, available technologies, raw materials, and so on). To accelerate economic growth, such a restriction can be overcome by inflows from outside the system (immigration, foreign loans etc.) by the overexploitation of production capacity, labor force and natural resources, and all these methods involve offsetting future expenses. Consequently, the amplification and limitation of restrictions generate effects that trigger a certain oscillation of the rate and level of production.

Each of the above categories is manifested in several ways, sudden onset or gradual development. As a function of this behavior we may identify: the moderate cycle (both effects are obtained gradually) the abrupt cycle (both effects occur suddenly) and the combined cycle (effects evolve differently). Because they occur in a development context, they were considered dynamic economic equilibrium cycles.

The second approach refers to "long cycles" (such as the Kondratiev cycles). Based on the research of technological, investment, social and demographic components, he identified three possible types of macrocycles: inertial macrocycle, sequentially controlled macrocycle and optimal macrocycle. The economic macrocycle is the long-term cycle of the society's productive apparatus. The indicators of the economic macrocycle are summary indicators of the national economy, in particular, the final product and the main destinations of its use, the employment level. Several explanations have been advanced regarding the long-term fluctuations: technological innovation, the entry into service of new resources, changes in agricultural production and wars, the thesis about the crucial role of technical progress cycles gaining ground. (Dobrescu, 1987: 186) The conditions to achieve the optimal macrocycle are numerous, considering the overall state of society. This implies the existence of an advanced economy with a strong field of scientific research and technological development. Through the existence of this sector, the country is able to ensure the training and the restructuring on new bases of its productive apparatus in the ascending phase of the macrocycle. In the absence of this sector and under conditions of excessive dependence on imported technologies, the macrocycle cannot be controlled or optimized.

Another condition is to establish social control over reproduction, so as to ensure real social and institutional conditions for the unitary coordination of the economic and social life, which are indispensable to the optimal macrocycle. A superior training for all members of society as well as a high degree of social homogeneity of the population are also required, in the direction of considerable closer working and living conditions. This creates the prerequisites for the understanding by the broad mass of people of the imperatives of long-term economic development and harmonization of interests of different social groups in order to shape the society's overall options based on a broad social consensus. (Dobrescu, 1987: 199-200)

The relative simultaneity of interdependent cycles produces in the economic development process an overall restructuring phase of the productive apparatus. Regardless of the manner in which it is produced (spontaneously or planned), such a phase is inevitable. The feature of this phase is the qualitative change of fixed means and informational background incorporating the results of technological innovation, while the scale and pace of restructuring process depend on the gross accumulation rate. (Dobrescu, 1987: 197)

The monetarist theories, which claim that at the origin of economic fluctuations there is the changing mass of money in circulation, were contradicted by the appearance of the theory of "neutrality of money". Economists, including *Silviu Cerna*, believe that the real sizes are not influenced by the general price level and thus changes in the monetary mass affect only the nominal indicators and not the long term real indicators. (Cismaș, Pitorac and Neamțu, 2012)

The neutrality of money is explained by the way in which the economic agents form their expectations: 'money is not neutral by nature, but is "neutralized" by the fact that, in their current decisions, businesses are considering the future.' Cerna, 2009: 678) Also, a distinction must be made between adaptive expectations, where money is neutral in the long term and rational expectations, where money is neutral in the short term. But all these can be influenced by the type of monetary policy adopted by the government. A discretionary policy can cause increased inflation and thus the expectations of the economic agents are no longer achieved and the currency gains an active character. (Cerna, 2009: 679-681)

The economist *Liviu Voinea*, in his book "Sfârșitul economiei iluziei" considered the crisis of 2008-2010 in Romania to be internal, it would have occurred even in the absence of the financial crisis that started in the U.S., and the external economic crisis was only the triggering factor of the internal economic crisis. (Voinea, 2009:36) The causes of this crisis are: (1) deregulation of markets, (2) the phenomenon of corruption associated with the mismanagement of funds, (3) the speculative bubble in the real estate market, (4) wages above productivity, which led to (5) increased consumption, which has become the main engine of economic growth and (6) private debt financing of exponential growth of the current account deficit, which exposed Romania to the volatility of international capital flows. (Voinea, 2009)

More recently, some economists, including *Alex Berca*, consider that the main causes of the crises can be found in (Berca, 2011:102-103): (1) undue inflation of some companies' stocks (as was the case with "dot.com" companies, which meant the loss of billions of dollars by private investors or financial institutions that had invested money in the stocks of such companies, (2) enormous financial fraud of the order of hundreds of billions of dollars, (3) onerous business of some banks or insurance companies that rose to the level of real fabulous amounts of the order of hundreds of billions of dollars and (4) detection of antisocial acts with a direct result on the sharp fall in the stock exchange, and many other financial aspects.

Another important cause of economic crises is overcapitalization, being more real than overproduction. The issue of overcapitalization is questionable, especially under conditions specific to an advanced capitalist economy and modern production. And the main factors that influence the development of the overcapitalization process would be (Berca, 2011:68): the financial industry in general and banking in particular, credit and insurance institutions, which in the contemporary capitalist economy become much more "dangerous" in triggering an economic crisis than the

manufacturing sector, which creates an abundance (overproduction) of products for the market.

The most cogent example is provided by the crisis of 2007-2010 caused by the lack of regulations, disregard or even breach of the regulations in the financial system, especially in the credit sector and which have come to have global effects. In addition, there is another factor – a non-economic factor, but with an important role in the onset and evolution of an economic crisis. "It is the human factor, human psychology, before, during and after an economic crisis. Panic caused by the risk of a crisis outbreak affects the large and small investors, the manufacturing entrepreneurs and those in the retail sector, who must substantially change their business." (Berca, 2011:68)

## **Conclusions**

This research was intended to carry out a comparative critical review of the Romanian economic theories on economic crises and cyclical fluctuations.

The main results obtained were:

- the identification of the main Romanian economists who were concerned on studying economic crisis and cyclical fluctuation in economy: Virgil Madgearu, Gheorghe Badrus, Costin Murgescu, Tudorel Postolache, Emilian Dobrescu, Silviu Cerna, Liviu Voinea and Alex Berca;
- the presentation of the Romanian economic theories that address the issue of economic crises and cyclical fluctuations in economy from which resulted that all these theories considered that cyclical fluctuations are caused by endogenous factors. Some of them, like Tudorel Postolache, Gheorghe Badrus, Costin Murgescu and Emilian Dobrescu, believe that technical progress and innovation are the main reason of cyclicity, others, Liviu Voinea and Alex Berca, considered market deregulation, corruption and overcapitalization being the causes of economic crisis, analyzing mostly the crisis from 2008-2010.

In conclusion, it can be said that a series of factors contributed to the onset and development of the economic crisis in Romania (technical progress, investment, production variation, corruption, overcapitalization), but the structural problems of Romanian economy determined the external factors to act decisively.

## A VIEW UPON THE HISTORY OF THE PEASANT ASSOCIATION

**Pop Stanca Alexandra**

*Department of Political Economy, Faculty of Economics and Business Administration, Babes-Bolyai University, Cluj-Napoca, Romania  
stanca\_pop@yahoo.com*

**Abstract:** *The whole social and economic life is based on some form of association. People live in societies, so the idea association appeared in the most natural way, at first in an unconscious form, moving later towards the conscious and organized association. Seeing that through the association they were able to defend their professional interests, fulfil their economic goals and meet their common needs, peasants adopted its formula with confidence. The ways in which the association spread were diverse. Depending on the economic, social and moral circumstances and on the habits and goals of the various masses of peasants, there have been developed mainly one of the three forms: trade unions, cooperatives, and mutuality. The peasant associations helped the rural communities everywhere and were the object of interest of many theoreticians, who sought their roots, their forms, presented their principles and analyzed their results. One of them was Professor Nicolae Ghiulea, a Romanian economist and sociologist, fervent supporter of the association idea.*

*Nicolae Ghiulea was among the most important representatives of the cooperative doctrine of the interwar period and was well-known for his prestigious academic career. He filled several administrative and social leading functions and had a rich publishing activity in the areas of statistical theory, social economy, cooperatives and sociology. This article sets out to present his view upon the history of the peasant association, as exposed in one of his books entitled „The peasant associations”. The author focuses on the various forms of peasant associations, their history and their practical results in interwar Romania, explaining why they were beneficial. At a closer look, peasant associations are still a viable solution to many current social issues, especially those concerning agriculture.*

### 1. Introduction

Born in Iași (11 September 1884), with an original background in Mathematics, Nicolae Ghiulea was a professor of social policy at the Faculty of Law of the University of Cluj (from 1919 until 1942, when he retired). His inclination towards Sociology came from a series of special sociological studies conducted in Paris, Göttingen, and Iași. He was an economist and a sociologist, filled outstanding administrative and social leading functions, and was one of the most important representatives of the cooperative doctrine in the interwar period. Ghiulea was one of the initiators of the social market economy in Romania and was known for his prestigious academic career and rich publishing activity in the areas of statistical theory, social economy, cooperatives and sociology.

The socio-economic issues in general and current problems of the interwar period

in particular were the main concern of Professor Ghiulea. As a fervent supporter of the idea of association, he found the solution to the shortcomings of the agrarian reform in Romania in the organization of peasant associations. This article sets out to present the various forms of peasant associations, their history and their practical results in interwar Romania, as Nicolae Ghiulea described them in his paper published in 1926, called *The peasant associations* (original title: „Asociațiile țărănești”).

Since ancient times, the man has been able to live and prosper by working the land. If early mankind allowed free access to natural wealth, with increasing population and scarcity of resources, property developed, and work began to be organized. The basic principle of economics, that of seeking maximum satisfaction with a minimum consumption of resources, caused the man to organize his work so that it would allow him to unfold activities for relaxation and personal development as well. In this respect, he followed three ways: invention, division of labour and association. Discoveries of any kind make human labour easier and more productive, division of labour maintains favourable economic and social relations between the individuals of a society, and the association increases people's strength to work and struggle, enabling them to develop and civilize.

In the period between the two world wars, a good organization of the agricultural work in order to improve the agricultural production and to resolve the land issue was imperative. For this, several aspects had to be taken into account. In terms of nature, the organization of agricultural work related to the scientific culture of the soil. Concerning capital, a good organization of labour in agriculture needed the procurement of working capital, farm machinery and buildings, from peasant savings or obtained loans. Finally, in terms of work, there were necessary the technical and commercial business organization in order to bring as much profit as possible, the insurance of labour against natural hazards, the division of labour and the concentration of production in large enterprises

## **2. The Consequences of the 1921 Agrarian Reform**

The agrarian reform of 1921 contributed to changing the course of development of the Romanian economy in general, and the agriculture in particular, as a result of modifying the structure of land ownership.

Another consequence was the fact that it accelerated the transfer from grain stage (wheat monoculture on large areas) to the alternative system based on crops with a higher return.

Due to its wide scope, the agrarian reform of 1921 was appraised as the greatest and most economically daring of the world. It was an act of social justice, accepted by the entire Romanian society.

Beyond its social character, almost universally recognized, the land reform was, however, criticized at economic level. The main objections (at that time) were related to de-industrialization of agriculture. The fact that small farms would not afford mechanized tools enabling higher yields and productivity.

Nicolae Ghiulea argued that the agrarian reform of 1921 was made without a thorough study, without serious training, without a well thought program. The problem was not achieving this reform, which was in fact urgently needed, but the inappropriate way in which it was applied and the improper means which were used. The negative consequences that followed referred to a lower production in quality

and quantity, then reduced exports and, finally, a worsening of the economic balance and of the exchange rate. There had been made a transition to the small-sized property, in which peasants worked their small plots of land they received with their own arms, but with primitive techniques. The unprepared disappearance of the large property thus contributed to decreased earnings from the agricultural production, a rise in the price of life and the collapse of the Romanian currency. All this caused the Romanian economy to enter a crisis.

The peasants suffered greatly. They encountered great production difficulties, due to the lack of tools, livestock, capital, and the lack of agricultural insurance organization that did not allow them to perform the agricultural work safely. In addition to this, they were obtaining very small gains, because of the high production costs and the low sales prices. The existence of a genuine agrarian crisis, of a total disorganization of the agrarian life could not be denied, therefore. The peasants were in an even lower economic situation than the one before receiving land ownership.

However, morally, the agrarian reform had beneficial effects. Peasants began to aspire to a better life; they had their appetite opened for culture and for participating in state leadership, which was an important incentive to work and progress.

With all the difficulties brought by the land appropriation, the action came on time and was extremely valuable. The superiority of the small-sized property regime over the great agrarian properties was recognized worldwide. The small landowner constituted an element of order and social equilibrium. Besides, the peasant landowners had the ability to culturally enhance the Romanian people. In order to spread and develop culture, general welfare was necessary. The regime of the great agrarian property provided a low level of civilization, since the majority of the population, who was employed in agriculture and lacked land, was living in misery. The small-sized property regime could be superior to the one of the great agrarian property even economically, provided that the agricultural labour was organized.

It was necessary to ensure a professional and economic education of the peasantry, removing restrictions on production and sales, and granting peasants full freedom to organize and defend. Hence, production was going to increase, exports also, and the situation of trade and currency was going to improve. Increased earnings would have determined the peasants to increase consumption, and the industrial and commercial activity would have thus intensified. This general welfare was going to lead to the state's welfare, to recovery and development. Moreover, with the introduction of the universal suffrage, Romania had a clear path to get among the strong and healthy democracies of thriving culture and civilization.

Nicolae Ghiulea believed that the association was the key to the organization of agricultural labour under small property, defining it as a means by which the man achieves, with others, that which he cannot achieve by himself. By association, the man increases his strengths and his action field, saves his forces and riches, increases his activity and its outcome, and reduces his damages resulting from disasters, dividing them among all. Ghiulea considered that the association was the most appropriate means for the organization of work in the form of small agricultural properties, as it also provides the harmony between the different social strata.

### 3. Forms of Peasant Associations

Less used in agriculture, the association in its perfected form was not introduced until later in the rural areas. The slow spread of the peasant association is explained by the peasant's economic individualism, the lack of importance and the rarity of the rural agglomerations, the isolated peasant life, and, last but not least, the lack of social education resulting in the distrust of fellowship.

In carrying the Romanian peasant life, since old times, there have been many expressions of a strong social sense, of mutual aid. History offers many models of associations formed in order to work together, or in order to commonly achieve economic or social benefits. Instinctively, the peasants associate and are open to the idea. However, explained Professor Ghiulea, the introduction of the organized and legal associations with high goals and of general interest was not easy to achieve without prior education in this respect.

The purposes of the peasant associations are diverse and can be divided into three categories: professional (for defending the interests of the small farmers), of cooperation (from the desire for a gain), or mutual (for satisfying common needs). The first group includes farmers' trade unions, organized in order to promote agriculture, ensure vocational education and take general measures of local interest.

In the second group we have the many types of cooperatives: of joint purchase (they are the most valuable and most easily to organize for farmers; through them villagers remove the intermediaries, buying directly from the manufacturer), credit cooperatives (offer cheap and fast credit), of agricultural production (one of the brightest, most common and most successful forms of production cooperative; through it, the small landowner can benefit from the advantages of the great property; the economic concentration decreases the production cost; the selling price increases), of storage or joint selling (useful for individual farmers, being sometimes imposed by the large buyers who refuse to make transactions with small individual producers), to industrialize and exploit animal and agricultural products (cooperative factories for oil, wine, textiles, dairy-cooperatives, cooperatives for egg trade, for wool trade etc.), consumption cooperatives (which, in addition to food and necessary goods, acquires housing to the peasant).

Nicolae Ghiulea believed that by organizing agricultural labour into production, exchange and consumption cooperatives, there could be obtained all the advantages of large enterprises, namely the capitalist organization, the division of labour and the concentration of production. Thus, the peasant would become the only master of his labour and the results of his work. The intermediaries and the speculators, in the person of usurers, merchants, great industrialists, owners or lessees would be removed and the peasant would find his freedom and his economic power.

Finally, the last category of peasant associations refers to mutual insurance associations, which cover all agricultural risks and allow peasants to share damages with their fellow associates. In this case, federalization and centralization of various local associations was considered of utmost importance, because agricultural risks often affect a whole region not only a common, requiring the organization of the reinsurance operation.

#### **4. The History of Peasant Associations**

Professor Ghiulea sought the roots of the peasant association in the works of the two associationist philosophers, Charles Fourier (France) and Robert Owen (England). Contemporaneous, these two cooperative promoters believed that the association was the ultimate solution to the social problem related to the injustice in the distribution of goods. Robert Owen contributed to the birth of the consumer cooperative, as an act of the urban cooperative movement. His ideas stood as an example for the Rochdale pioneers, the founders of the modern cooperative. On the other hand, from the ideas conceived by Charles Fourier, the industrial production cooperative was born, also as an act of the urban cooperative movement.

These two socialists deserved to be mentioned here because both based their plan of world reformation primarily on agricultural associations. Fourier imagined those economic and social associations called „phalanxes”, which actually stand for the complete consumer cooperative. These phalanxes were also complete production cooperatives, because they were intended to produce everything necessary for living in the association. They were therefore integral cooperatives, based on agricultural work and production, as associate members were primarily farmers, and sporadically craftsmen and industrialists. However, because the phalanxes expected a certain level of culture, they were inaccessible to farmers and their influence upon the agricultural associations was null, being manifested only within the worker agglomerations. Nicolae Ghiulea believed that although phalanxes could not be counted as parables for the creation and development of the agricultural association, they bred the idea of association under all its forms, as they gave rise to the idea of the modern cooperative that Fourier did not think about and which he would have never admitted in his system.

Robert Owen was also a utopian idealist, but unlike Fourier who had a modest financial situation, he had the financial ability to put into practice his plans for social transformation. He started his social activity through a number of patronal measures to improve the situation of the workers at his factory in New Lanark. Then, wanting to expand his ideas, he turned to the English government and to the governments of other countries, contributing thus to the development of laws for the protection of workers. Trying to spread ideas among the other industrialists failed, because of the greed that characterized them.

Observing the misery of workers everywhere determined him to develop a system of social organization in which all the sufferings and all the evil were removed. Thus the idea of agricultural peasant associations called „communities” was born. Owen believed that reforming the world could only be achieved by creating a new social environment, and that environment could only be at the countryside, where there were the virtues and the wealth needed for the ideal world he dreamt about. Owen's doctrine, said Ghiulea, was an agrarian doctrine, whose central idea was the association, namely the peasant association as an ideal of social organization.

These communities were founded on communist grounds, everything except the family life evolving jointly: production, distribution, public life. His most important achievement was the New Harmony community in the U.S. state of Indiana. But practice did not comply with theory, and what was meant to be an organized community, turned out to be a society in a profound anarchy.

This experience that had cost Owen and other American philanthropists enormous sums, proved that Owen's system was nothing but a unrealizable utopia. However, the desire for social transformation that Owen had inspired to the whole world caused, in terms of politics, the birth of the international and democratic socialism, in economics terms, the genesis of cooperatism and trade unionism, and morally, it created the mutualism.

The economic and social circumstances in France and England, and more specifically the speed at which the transition from feudalism to capitalism was made, gave rise to the two cooperative movements: the production cooperative, imagined by Charles Fourier and the consumption cooperative, implemented by Robert Owen. In England, the rapid development of the large industry and of mechanization caused the misery of workers, who lost their jobs, the only way to improve their living being their association in consumer cooperatives. In France, on the other hand, the large industry developed more slowly, but it contributed to the progressive decline of craftsmen, who found the solution for survival by organizing production cooperatives. The cooperative movements in England and France became known abroad, and thus the idea of association spread worldwide.

Through its economic side, the cooperative idea won Hermann Schulze and through its Christian side, it captivated Friderich Wilhelm Raiffeisen. The two Germans were the founders of the two famous cooperative models: the urban cooperative (the Schulze-Delitzsch system) and the rural cooperative (the Raiffeisen system). The principles established and imposed by these two systems, along with the one of the „Rochdale Pioneers” – the fathers of the consumer cooperative – can still be found throughout the current cooperative movement.

Hermann Schulze turned his efforts to organize production cooperatives in order to help the craftsmen who were overwhelmed by the large industry, but the biggest success he recorded was with the organization of the urban credit cooperatives. The one who came to answer the needs for rural credit was Friderich Wilhelm Raiffeisen, considered by Nicolae Ghiulea the inventor of the peasant association, the founder of the rural cooperative. When, in the mid nineteenth century, there could only be heard the cry of the industrial workers who were in misery because of proletarianization, Raiffeisen focused on helping the farmers through the establishment of popular banks intended to eliminate the usurers who provoked them suffering. Raiffeisen's movement showed that, for the success of cooperatives in villages, first it was necessary to establish credit cooperatives. This was normal, as long as the farmer could not do the work without capital, and in his absence, without credit. Raiffeisen completed his cooperative model with the organization of the production cooperative. That was the path Romania chose as well.

In Romania, the Saxons were the ones who brought the idea of cooperatives. They started founding, since 1852, credit cooperatives of the Schulze-Delitzsch type, and later, after 1865, they established in Transylvania the credit cooperative following the Raiffeisen system. Romanians' first attempt was made in 1868 and belonged to a teacher named Visarion Roman, who founded, in Rășinari, „The Society for Storage and Loan”. This association operated for only 13 years, because of the lack of interest shown by the peasantry and a poor leadership. Although it did not precede a cooperative movement in its true meaning, the company determined the establishment of numerous popular banks that followed its example. Roman

Visarion continued to set up other associations called credit reunions, which he subsequently attached to „Albina” Bank, the first Romanian bank, whose director was until his death. From the beginning, the „Albina” Bank was regarded as the protector and the mentor of the popular peasant banks in Transylvania, operating 19 credit reunions, branches of the parent bank. The lack of independence of the reunions led to their discontent and to the suppression of the cooperative movement. „Albina” Bank opposed to their desire for freedom, liquidating them one by one, causing the end of the cooperative movement initiated by Visarion Roman. The teacher had thought, absurdly, that a commercial credit enterprise was able to support a cooperative movement and protect the popular banks, based on totally different ethical and economic principles than commercial banks. Without having any connection with „Albina” Bank, the only popular bank who survived in those times was the credit reunion „Aurora” in Năsăud, founded in 1873, which had a very great importance, because it served as a model for the first credit unions established in the old kingdom.

Unlike in other countries, where the cooperative movement started in cities and was then propagated in rural areas, in Romania the cooperative was born in villages and the first cooperatives established were the popular banks. Nicolae Ghiulea explained why in Romania things were different. The cooperative is an economic association that requires a certain level of culture, a deeper understanding of the economic and social statuses. Cities with a higher cultural level are better prepared for the cooperative idea than villages. In addition, the cooperative does not only claim culture in order to be understood and embraced, but it also claims an urgent economic necessity that would find its relief in cooperatives. The mid-nineteenth century and a few decades after, however, found the Romanian cities in a more than acceptable state. The transition from feudalism to a regime of liberty culturally raised the urban, while villages began to decline. In the cities, there was no need for a cooperative movement and P.S. Aurelian’s failure of the cooperative propaganda made in 1870 stood as a proof. Instead, the spread of the cooperative movement in the Romanian villages that were in misery was imperative. The Rural Laws of 1864 and 1866, which granted freedom to peasants, caused them more harm than good, as they ended up being greatly exploited by the landowners. Through their revolts in 1888 and 1891, the peasants did not achieve great benefits, their situation continued to degrade and they became victims of usurers’ speculation from the need for credit to buy food.

The peasantry’s moral and economic misery after 1888 was indescribable. The first ones who noted the need to raise the peasantry economically and morally were the teachers. With immense efforts and dedication, taking the examples of the Transylvanian credit reunions, they started spreading the association ideas in old Romania’s village life. Therefore, in 1891, they founded the first cooperative in Romania. It was the popular bank „Dumitra” in Dara village, Buzău. The cooperatives flourished there, like in Transylvania, in the form of the credit cooperative, as the peasantry’s most pressing need in those days was for credit and removing usurers.

The Romanian experience verified the truth that the cooperative succeeds only where it fulfils a real function and meets well felt necessities. In addition, the cooperative was not founded in a mountainous area by accident. Mountain counties

have always been superior culturally and economically, which is a necessary requirement for a successful cooperative movement. Although it started its activity like the Rochdale pioneers with a very small number of members (34) and a small capital (127 lei), the credit cooperative in Buzău was the initiator of the Romanian cooperative movement. After two years of adjustment with the idea of cooperatives, a priest named Diaconescu founded in Dâmbovița the second popular bank called „The Peasant”. Later, five other cooperatives were born, all in mountain areas. After a brief stagnation, starting with year 1896, the cooperative movement saw a great upswing, being established within 10 years 711 credit cooperatives in rural areas. The cooperative expansion in the years 1899-1902 was due, in part, to the support of Spiru Haret, the Minister of Education, who encouraged teachers to spread the valuable idea.

In 1903, the law on popular village banks and their Central House was promulgated in order to coordinate a movement that exploded impressively. Rather than offer them the freedom of federalization, the law made the mistake of involving the state and imposing centralization. The consequences were an accelerated and artificial development and the alienation of the cooperative movement from its fundamental principles.

Cooperatives were given a number of administrative, fiscal and judicial advantages. The new organization increased the number of cooperatives, and although many of them were born from state order, with the help of the Central House most attempts succeeded, defining a remarkable cooperative movement in Romania. The Central House, always led by skilled people committed to the movement, contributed greatly to the cooperative's progress in all directions. In 1905, the idea of federalization was introduced in the law on popular banks. The Central House deeply imbued with the cooperative spirit, encouraged cooperatives to establish federals, in order to be able to maintain their autonomy and act decentralized.

The success of the popular banks in solving their financial problems urged farmers to focus their attention on their second worry, namely the lack of land, whose solution was also the association, through the establishment of the communities for leasing land. The leasing communities' benefits were on both sides: peasants received land, and the owners received larger rents, also having the assurance that their lands were well cared for and rationally cultivated.

The problems concerning usurers and leaseholders being removed, peasants needed further to eliminate merchants through the organization of the consumer cooperative. The movement started after 1906, but its way was difficult. However, while in 1907 there were 91 consumer cooperatives, in 1923 there were 2690 consumer cooperatives recorded. Slowly, the cooperative was extended to all industries. The fruitful cooperative idea made it possible for peasants to help each other with all the hardships of their economic lives. The production cooperative was the one that came to complete the Romanian cooperative movement. Starting with year 1905, there have been established numerous forms of production cooperatives (bakeries cooperatives, mills cooperatives, dairies cooperatives, purchasing and joint selling cooperatives et.), all signs of a brilliant development of the Romanian cooperative.

## **5. In conclusion**

The results of the peasant associations in Romania were not at all modest. The Romanian cooperative movement started later than in the developed countries, but the cooperative idea was embraced by the Romanian peasants in a remarkable way. In a short period of time, most villages had at least one cooperative association.

The local needs and the various shortcomings led to the organization of mixed cooperatives in post-war Romania. They were called mixed because they were ultimately production cooperatives, but they also acted as joint supply cooperatives (of both materials, machines and tools required in the production process and the items necessary for the daily living), specific to the consumption cooperative association, and joint selling (simple selling plus semi-transformation of products). This was the kind of cooperative that spread in our country, meeting all the interests of the peasantry and taking agricultural unions' place, unknown in the Romanian villages. Their well-written status introduced in Romania the fundamental principles of the pure cooperative.

The pre-war village communities (for land leasing) disappeared after the land appropriation for various reasons, such as the fact that the peasant did not think it would be the appropriation beneficiary but those who led the community, or the poor results of some communities seized by the state. After the war, few communities were created, and their activity was reduced. Ghiulea thought that it was unacceptable the decline of the cooperative movement through communities, which had been so flourishing and represented the Romanian specific of cooperatives. The professor believed in the utility of the communities for the future, when the fragmented lots would not be sufficient for a family living.

Nowadays, the excessive fragmentation of land does not allow the establishment of productive farms, but mostly the achievement of the family economy. The simple peasant, lacking sufficient funds, does not have the technical equipment needed to make a profit from agriculture. That is why any forms of association are still opportune today. Moreover, Romania can benefit from the European Union's support as well, in order to improve agriculture's profitability, so it has a solid ally towards its overall economic development.

nicoleta.sirghi@feaa.uvt.ro*

**Abstract:** *The neoclassical theory of the firm deals with the pattern of perfect competition, within which the perfect information available to economic agents provides instant allocation of production factors and access to economic goods. The Austrian School (C. Menger, L. von Mises, Hayek, etc.) supported the idea of minimal state intervention on the markets, bringing important conceptual developments on the theory of the firm. Hirschleifer (1982) put forward the model of social and institutional functioning, arguing that the game theory is able to predict the outcome of the collective behavior and the human characteristics necessary for building the respective institutions. The evolutionary theory provides the firm and the entrepreneur the recognition of the functions of innovation, of generating and exploiting information and of organizing and coordinating production. The evolutionary perspective of the firm assumes the existence of a body of knowledge that is acquired through and builds up the organizational memory, subsequently found in routines, all choices being made based on these routines (Nelson and Winter, 2002). The evolution of the firm is considered to be similar to natural selection, but unlike the classic market selection, the evolutionists suggest the existence of a plurality of selection media. The present research is structured as follows: a brief introduction into the theories of the firm, the second part of the paper analyzes the theories of the firm from an institutional, neo-institutional and evolutionary perspective. In the third part of the paper the evolutionary games are described and analyzed from the evolutionary perspective of the firm. The last part of the paper represents a study of the “hawk-dove” game dynamic replicator. The final conclusions of the paper show that the evolutionary theory brings valuable contributions to the foundation of explanations regarding economic phenomena, indicating new directions for advanced economic research.*

**Keywords:** *theory of the firm, game theory, evolutionary theory, evolutionary games, dynamic replicator.*

## 1. Generally Introduction

In this chapter we shall identify the main views on the firm expressed by the Neoclassical Economics and the Austrian Economics and we shall present the main theories of the firm. If in the case of a perfectly competitive market the firms are of approximately equal sizes and cannot influence price formation, in the case of imperfect markets the competitive behavior of firms show that they are in active competition with each other and have some power to influence the market. The analysis of market structures is useful in identifying different types of markets, providing information on the performance of firms. The paradigm on structure,

conduct and performance (Chamberlin 1933, Bain 1956) dominated economic thought until the '80s. According to this paradigm, the structure of the market in which firms operate is ultimately the determining factor of performance and is measured through indicators such as profitability. The Neoclassical theory deals with the pattern of perfect competition, within which the perfect information available to economic agents provides instant allocation of production factors and access to economic goods. According to the neoclassical theory, the firm exists to combine production factors to achieve and maximize profit (Coase 2002).

Harvard School (J.S. Bain, E. Mason, etc.) became well-known due to the conceptual research done on the structure and functioning of markets, barriers to entry, competitive strategies, economies of scale, transaction costs and antitrust cases. Contrasting the paradigm on structure, conduct and performance, the Chicago school continued to use an approach based on the neoclassical model of long-term equilibrium in competitive markets. Thus, the resources are allocated optimally and the market is the one that has the power to balance supply and demand. The representatives of this school (A. Director, G. Stigler, W. Baumol, etc.) studied the theory regarding the life cycle of the firm, the firm's power on the market as a determinant of its integration. A significant contribution belongs to W. Baumol (1982) who promoted the theory of contestable markets, assuming that markets become competitive in the long term, and government interventions are not always considered necessary.

The Austrian School (C. Menger, L. von Mises, Hayek, etc.) supported the idea of minimal state intervention on the markets, bringing important conceptual developments on the theory of the firm. We observe such research on the competitive structure of markets, those relating to the dynamic nature of markets, as well as the research on the characteristics of firms, sectors and markets. Starting from the research done by Carl Menger and Eugen von Böhm-Bawerk, Mises Ludwig von Mises (1881-1973) helped develop theories of the firm showing that giving up private ownership of production factors makes price formation and entrepreneurial calculation in monetary terms almost impossible. More recently, researchers that may be considered as followers of neo-Austrian school, such as Kirzner (1913), Reekie (1984) and Littlechild (1986) used the term "evolutionary economics". The theory of evolutionary economics has developed in parallel with the institutional economics. Basically, it is about the endogenous view according to which the beliefs, norms and customs of the society could lead to the formation of institutions that facilitate corporate behavior. Hirschleifer (1982) put forward the model of social and institutional functioning, arguing that the game theory is able to predict the outcome of the collective behavior and the human characteristics necessary for building the respective institutions.

The research called "An Evolutionary Theory of Economic Change" (Nelson and Winter 1982) represents the starting point and a reference for the trend addressing the theories of the firm from an evolutionary perspective (Arena and Lazaric 2003). Nelson and Winter (2002) have criticized the neoclassical theory considering that the profit maximization assumption is not valid in all cases, indicating that excessive attention is not to be allotted to market equilibrium, but rather to dynamic processes arising from economic exchanges exposed to risk and uncertainty. In economics, the concept of evolutionism has resulted in an institutional type of evolutionism. One of the most important authors who advocated for evolutionary type approach was Friedrich A. Hayek, who observed that efficiency is approached from a dynamic point

of view, contrary to the neoclassical theory where the approach was from a static point of view profit maximization.

The evolutionary theory defines the firm as a set of essential skills, gathered based on its learning ability. The evolutionary approach adopts the concept of limited rationality, the individuals and the organizations have much to learn in a complex environment characterized by uncertainty in the context of the knowledge economy. From this perspective, the firm is regarded as being a coherent system of activities associated with the production of synergistic effects (Gould 2002).

## **2. The institutional and neo-institutional perspective on the theories of the firm**

The Walrasian model (1873) was imposed, economics focused exclusively on production and consumption. Postulating institutions and rational behavior made it possible to develop mathematical models by which the interaction on the free market could be conceptualized. Thorstein Veblen (1899) argued the need for a reorientation of the economic theory from the exclusive concern regarding individual choices towards the study of institution's impact and evolution. John R. Commons (1931) advanced the idea that the economy is defined by institutions and conflicts of interest. The institutional paradigm developed as a reaction to the tendency of economics' specialization on supply and demand issues, ignoring the problem of institutions that enable the functioning of markets (Veblen 2005).

Knight (1921) paved the way for highlighting the role of institutions in reducing uncertainty, and Coase (1937) showed that an institutional framework conducive to economic development is one that reduces uncertainty and transaction costs. The framework developed by R. Coase is the one that reduces transaction costs so that participants in the economic game to take advantage of market opportunities.

The institutional perspective on the theory of the firm is closely related to the issue of transaction costs, of uncertainty, and of innovation (Sherer (1967), Stoneman (1983), Doris (1989) and Reingenum (1989)). Institutions influence behaviors through information on individual action, social overseeing and fostering cooperation (North 2007). The basic idea of institutionalism is that institutions create economic game rules, generates economic incentives, and these incentives influence the behavior of economic agents. The institutional system generates incentives with specific and predictable effects on the behavior of decision-makers, contributing to the efficient allocation of resources and stimulating the flow of innovations.

The hypothesis put forward by O. Williamson were considered and applied: in the history of economics (North 1981), in the game theory and organizational economics (Alchian and Demsetz 1972, Nelson and Winter 1982, Grossman and Hart 1985). Until the '90s, the dominant school of economic thought continued to produce models that excluded the institutions from among the relevant factors. North (1990) considered as a source of transaction costs, the overall costs of maintenance and operation of a property rights system in the conditions of increasing specialization and labor division expansion. These economic theories make up the group of institutional theories on rational choice and set the transition from institutionalism towards neo-institutionalism.

A significant element, approached by the institutional economics is represented by the identification of socially optimal exchange structures to ensure maximize wealth. This requires a functioning market system in which economic agents will select those rules that will allow them profit maximization. Rational individuals compete not only

to maximize benefits under a specific set of rules, but they also try to change these rules and obtain higher earnings (Demsetz 1972).

Neo-institutionalism provides recognition for the contributions of the neoclassical school of economic thought, using both quantitative and experimental methods to solve relevant issues (Diermeier and Krehbiel, 2003). A number of authors (Meyer and Rowan 1991; Williamson, 1991; Kalai and Lehrern 1993, Foss 1994, Langlois 1996, Joskow 2002, Aoki 2005) studied the efficacy issue of alternative mechanisms of governance as well as the role of institutions in generating economic performance by lower transaction costs.

The existence of institutions, whatever form they adopt, is subject to selection processes depending on the environment and mental constructions of individuals. From a set of institutions, the individuals can choose a type of institution that lasts over time. This phenomenon has three explanations: the first is related to the evolutionary theory in biology, where the processes of selection, learning and imitation find their explanation; the second path concerns ideology, the changes occurred in social values which represent a major factor in institutional change; the third explanation concerns the set of rules that individuals have become accustomed to even if they are harmful and can lead to inappropriate behaviors.

Assuming that rationality is limited, it is considered that individuals, even if they have access to new information, operate under pre-existing mental constructions. In this vein there can be perceived a return to the Austrian school (Simon and Hayek), which integrates the two concepts in the analysis: limited rationality and procedural rationality. If the first concept was integrated in a shorter time, for the second it took a while longer. Kalai and Lehrern (1993) get closer to the Austrian approach by introducing the notion of subjective rationality of players. The only condition they admit is that the players' beliefs are updated through learning.

Aoki (2005) introduced in the analysis of institutions the idea that individuals have subjective representations of strategic profiles. The notion of mental models, which Denzau and North (1991) have used to justify the importance of institutions, is consistent with the Austrian view of rationality. The individuals are subject to a set of rules not because they understood them, but to respond effectively to environmental changes. The rules that allow groups that have adopted them to thrive and grow are imitated allowing the guidance of individuals' behavior (Garrouste 2007). These are ways of acting which individuals do not need to understand explicitly, they represent procedural rationality.

Below we present the evolutionary perspective that suggests a long-term analysis of the company's behavior on adapting to the competitive environment of the market, this adjustment being made based on random processes as well as on the identification of new routines.

### **3. The evolutionary perspective of the firm and evolutionary games**

In biology, the concept of evolutionism is closely linked to that of natural selection. The mechanism of evolution is explained by the fact that members of a population differ among themselves by different traits. Among these, only some features represent an advantage, and the individuals that hold them are better adapted to the environment than others. These individuals will survive longer and have more off spring, the traits are passed on through genetic inheritance, helping their survival within that respective population.

D. Bacaicoa and A. Brazales (2004) compared the properties of the human action theory formulated by Ludwig von Mises and Friedrich Hayeck's spontaneous order with the appearance of emerging properties, of self-organization and path dependency in the complexity theory. The evolutionary theory of the firm refers to complex systems, including economic ones, in which there operate independent network composed of multiple agents acting according to internal rules.

The evolutionary theory deals with the innovation activity as irreversible enlargement process regarding the complexity of economic activities. According to evolutionists, knowledge, the skills, the learning have central place in encouraging the innovation process, constituting its core.

Uncertainty is caused by the increasing complexity resulting from continuous changing of the economic and social reality and from an increasing number of variables that have to be considered. Institutions are seen as factors reducing uncertainty, the evolutionary theory recognizing competition, imitation, cooperation and domination as elements of survival in the market. The dynamic character of firms is endogenously generated by innovation in products, processes and organizational forms.

Organizational routines materialize knowledge generated by learning, being generated by repeated interaction between agents and environment. Routines are defined as patterns of interaction which represent efficient solutions for specific problems. Learning is conceived as a collective process that allows each individual to overcome the limited rationality by three factors: the relationship of imitation and emulation among individuals; their joint contribution to the understanding of complex problems and the existence of a common code of communication and of some coordinated procedures to search for solutions (Smith and Szathmáry 1997).

The company's development process is guided by the identification of new routines that are subject to selection at market level. In this configuration, the existence of production resulting from the behavior of firms and market conditions is one that opposes the traditional concept of market structures configuration (Dosi, Teece and Winter 2008).

The evolutionary theory defines the firm as a set of essential skills, gained from its learning ability. The evolutionary approach adopts the concept of limited rationality, individuals and organizations have much to learn in a complex environment characterized by uncertainty in the context of the knowledge economy. From this perspective, the firm is regarded as a coherent system of activities associated with the production of synergistic effects (Gould 2002).

The company's development process is guided by the identification of new routines that are subject to selection at market level. In this configuration, the existence of production resulting from the behavior of firms and market conditions is one that opposes the traditional concept of market structures configuration (Dosi, Teece and Winter 2008). In what follows, starting from the evolutionary perspective, we shall investigate the evolutionary game class of firms using modern and generous sets of instruments offered by the game theory.

The evolutionary games were first used and applied in evolutionary biology (Taylor and Jonker 1978, Maynard-Smith 1982). Since the 60s and 70s there was an increase in interest regarding the application of the game theory in biology, particularly stochastic games, the games of 'n' people with non-zero sum and those in extensive form. Lewontin (1961) has shown that stochastic games can be used in the study of the evolutionary problems of species. Turner and Rapoport (1971) have

discussed the concept of preference in economics and biology. Marchi and Hansell (1973) considered the evolutionary type processes and biological studies on non-cooperative game. Dawkins (1976) and Selten (1978) presented a mathematical analysis of associated strategies for stable and non-cooperative equilibriums. Strategic interaction, identified in biology, regarding obtaining the gain is further developed and applied in the field of economy. Therefore, there were identified solutions to evolutionary economic games such as Nash type equilibrium ones (NE) and multiple selection (Binmore 1991, Fudenberg and Kreps, 1993, Samuelson and Zhang 1992). Evolutionary games were developed as a distinct class of economic games based on the pioneering research of Robert Axelrod (1997). The class of evolutionary game was designed to reflect gain survival and maximization. Evolutionary game models are suitable to explain the existing interaction in a large population of individuals. Many of the applications of biology on routine, myopia and genetic transmission of behaviors can be successfully applied today in business (Gould 2002). Based on the dynamic behavior of systems in the long run and on aspects related to learning and development, we are witnessing an expansion of the range of economic applications of evolutionary game which include: models of cooperative and non-cooperative games, repeated games, sequential games, stochastic differential games, and progressive games. Among these are distinguished as important the stochastic evolutionary games providing a simple framework for describing strategic interactions between a large number of players providing static stable equilibrium (ESS) and dynamic replicator (Tembine 2007). In the literature in the field the evolutionary games are becoming more present although their economic applications are still quite isolated (Friedman 1991, Maynard-Smith and Szathmary 1999, Hofbauer and Sigmund 2003 Tembine H. et al., 2007). Further we analyze the evolutionary game model by studying the delayed dynamic evolutionary games. The evolutionary game model studies the behavior of populations made up of a large number of individuals who repeatedly engage in strategic interactions, the result of every individual depending not only on his/her own choice, but also on the choice of others (Samuelson and Zhang 1992; Sandholm 2010 ). Regarding the durability of cooperative behavior between individuals the evolutionary game model uses the prisoner's dilemma game in studying the development of the cooperation behavior between individuals (Zhang's., 2011, Zhang et al. 2011, Zhen and Perc 2010).

In a real competitive environment affected by risk and uncertainty, there are considerable differences in performance between firms that interact in the market. The dynamic model associated with evolutionary games can be studied using the tools of dynamical systems theory, the stochastic processes theory and the game theory. An evolutionary game expresses a formal model of strategic interaction, characterized by the fact that there will often be chosen strategies that generate high gain at the expense of the ones generating lower gain, and the players will not influence the future actions of other players (Friedman 1998).

#### **4. A study of the “hawk-dove” game’s dynamic replicator**

The dynamic Replicator describes the frequencies by which various adopted strategies may vary over time (Alboszta and Miekisz 2004, Friedman 1998) and the players’ gains depend on the frequency with which strategies are adopted within a population (Yi, T., Wang, Z., 1997).

Starting from the evolutionary game characteristic, i.e. the time evolution of strategies, in the literature in the field we identify the problem of the discrete approach of the dynamic replicator, the study of the conditions necessary for the for stability and the introduction of the delay in two different models: the social model and the biological model (Alboszta and Miekisz 2004).

Tembine et al. (2007) conducted a presentation of the dynamic replicator by which they described the evolution of strategy frequencies within the population and they studied the stability of the equilibrium point depending on delays. This study will continue in this pattern, taking into account the stochastic case in addition.

In the dynamic evolutionary games checked will be usually only the conditions for which the equilibrium is stable. In the proposed model we shall study the effect of delay on the stability of the dynamic replicator. The delay occurs due to the fact that the outcome of a decision is not instantaneous, so there is a period of time between the decision and its effect.

We consider that each pure strategy corresponds to a delay. We consider an infinite population of players, and each player chooses a pure strategy out of the S set of strategies where  $S = \{1, 2, \dots, n\}$ . It is assumed that only pure strategies are considered, i.e. each player chooses one strategy only.

The matrix of gains will be noted with A. Because players will interact in pairs, the matrix A is expressed by the relation:

$$A = (ka_{ij}), i, j = 1..n,$$

Let  $x \in \mathbb{R}^n$  be the n dimensional vector, called the state of the population, for which the component  $x_i$  is the frequency by which the strategy "i" is adopted.

The gain function of the player following the strategy "i" and "f<sub>i</sub>(x)",  $i = 1..n$  is given by the relation:

$$f_i(x) = k \sum_{j=1}^n a_{ij}x_j$$

If a player chooses the "i" strategy at a certain time "t", then the expected gain is expressed by the equation  $f_i(x(t - \tau_i))$ , where  $\tau_i$  is the delay corresponding to strategy "i" and  $x(t)$  is the state of the population at the time "t".

The dynamic replicator is given by the equation (1):

$$\dot{x}_i(t) = x_i(t)(f_i(x(t - \tau_i)) - F(x(t))), \quad i = 1..n \quad (1)$$

Where:  $F(x) = \sum_{k=1}^n x_k(t)f_k(x(t - \tau_k))$  is the medium gain of the population.

Strategies that generate higher expected profits quickly spread at population level.  $X_0$  will be considered as the equilibrium. The right side of the system (1) is equal to zero in the  $x_0$  equilibrium point. Thus, the following conditions occur:

$$x_{0i} = 0 \text{ sau } \sum_{j=1}^n a_{ij}x_{0j} = \sum_{k=1}^n \sum_{l=1}^n a_{kl}x_{0k}x_{0l}, \quad i = 1..n$$

Further shall be considered the simplified case with only two strategies for which the matrix for gains is  $A = (ka_{ij}), i, j = 1, 2$ , and the gain functions associated with each strategy are:

$$\begin{aligned} f_1(x(t - \tau_1)) &= k(a_{11}x_1(t - \tau_1) + a_{12}x_2(t - \tau_1)) \\ f_2(x(t - \tau_2)) &= k(a_{21}x_1(t - \tau_2) + a_{22}x_2(t - \tau_2)) \end{aligned} \quad (2)$$

The medium winning of population  $F(x)$  is provided by the relation:

$$F(x(t)) = k(x_1(t)(a_{11}x_1(t - \tau_1) + a_{12}x_2(t - \tau_1)) + x_2(t)(a_{21}x_1(t - \tau_2) + a_{22}x_2(t - \tau_2)))$$

Considering the assumption that each player takes a single pure strategy, we determine the dynamic replicator expressed by the equation (3):

$$\dot{y}(t) = -kdy(t)(1 - y(t))(\alpha y(t - \tau_1) + \beta y(t - \tau_2) - y_0) \quad (3)$$

where:

$y(t) = x_1(t)$  represents the frequency of players who adopt a strategy at the time  $t$ ,  
 $0 < y_0 < 1$  and  $y_0$  is the only equilibrium point:

$$d = a_{21} - a_{11} + a_{12} - a_{22}, y_0 = \frac{a_{12} - a_{22}}{d}, \alpha = \frac{a_{11} - a_{12}}{d}, \beta = \frac{a_{21} - a_{22}}{d}$$

In “hawk-dove” model game, analyzed by Smith and Price (1973), the “hawk” is represented by players who adopt strategies of aggressive type, while the “pigeon” is represented by the players who adopt peaceful strategies. The model of the “hawk-dove” game serves to analyze the conflict between aggressive and peaceful strategies.

The numerical simulation was performed with two players, each player having only two strategies. Implemented on a duopoly market, the “hawk-dove” game refers to two firms which have to choose between two types of strategies: non-cooperation on the market (NCI) and market cooperation (Ci).

Ordering the four outcomes of the game can get the game winning matrix of “hawk-dove” type, shown in Figure 1.

		The player B	
		NC <sub>B</sub>	C <sub>B</sub>
The player A	NC <sub>A</sub>	(-0.5;-0.5)	(1;0)
	C <sub>A</sub>	(0;1)	(0.5;0.5)

**Figure 1:** The matrix of gains for the “hawk -dove” game

Figure 1 shows that in the case of the classic game of “hawk-dove” type (Smith and Price, 1973), the matrix for gains (A) integrates the following components:

$$a_{11} = -0.5, a_{12} = 1, a_{21} = 0, a_{22} = 0.5. \quad (4)$$

In this particular case the dynamic replicator will be given by the equation (5):

$$\dot{y}(t) = -kdy(t)(1 - y(t))(1.5y(t - \tau_1) - 0.5y(t - \tau_2) - 0.5) \quad (5)$$

The equilibrium point of the dynamic replicator's equation (5) is  $y_0=0.5$ .

## 5. In conclusion

In conclusion, the theories of the firm contribute to the foundation of explanations regarding phenomena of the real economy. By their use, as a frame of reference in representing the behavior of economic agents, these opened the way for a large field of investigation.

The problem of microeconomics is not to study the functioning of markets anymore, but to examine the ways in which firms can coordinate their decisions based on dynamic configurations in a competitive environment affected by risk and uncertainty.

The developments registered in the field of the theory of the firm lead to the conclusion that economics opens a large research area that can certainly be extended towards advanced economic research.

**Abstract:** *The insurance industry has an essential economic importance. In spite of the great progress, we have to emphasize that the existing theoretic models cannot entirely explain the mechanism of the insurance market and of its decisional process, especially in the case of the events with low probabilities. That is the point where the behavioral economists come with a larger view of the factors that influence the consumer decision explained through the Prospect Theory of Kahneman and Tversky, through the Cumulative Prospect Theory that represents an enhanced view of the Prospect Theory and Prelec function. The concept of utility is also detailed in some extent in this paper contributing to a larger perspective about decision in insurance market and its role in the development of insurance market. Prospect theory tries to emphasize the role of psychological effects upon the consumption decision showing that the economic agent does not have a rational behavior and is not risk averse in all situation. In this paper there are showed and debated some situation in which psychological effects like loss aversion, reference point, status-quo and framing effects can influence the decision of the consumer and are not consistent with the standard economic model. In addition to this aspects, Cumulative Prospect Theory enhance the fact that decision makers overestimate low probabilities and underestimate high probabilities, thus buying inadequate insurance in many situation. In this sense, in order to support this idea I tried to make a qualitative presentation of the model used on the insurance market using Prelec function which is the function related with the Cumulative Prospect Theory which can be used in the insurance context. The weak points of the theory of expected utility are explained through this new perspectives and nevertheless aspects like insensitivity to bad news concerning incomes, elasticity of price, displacements of status-quo and default, disposition effect and equity premium are taken into consideration. As example, I chose a Kunreuther experiment about insurance decision in which is underlined the fact that for moderate risk people buy insurance with premiums that exceed the expected loss. There are demands for low deductibles in the markets for extended guarantees and insurances for mobile phones where was observed that the insurance underwriting rate increases with the probability of loss keeping the expected loss constant. It is better to mention that the theory and the model that are presented here comes as complementary to the economic standard theory not as a substitute.*

## 1.Introduction

In the insurance market people are supposed to act as rational human beings and have a tendency for risk aversion in all situations. But as we will see this is not a general law and people tend to avoid insurance and misunderstand the probabilities. They take different reference points related to their wealth or emotional stimulus and because of this tend to overestimate low probabilities and underestimate the high probabilities thus making vicious insurance decisions.

There are several standard theoretical statements regarding insurance decision and behavior in the insurance market, namely:

- decision makers overestimate low probabilities and underestimate high probabilities.

- decision makers tend to ignore very low probability events and cataloged events with very high probability of occurrence to be sure.

- the consumers buy inadequate insurance in spite of the low probabilities

- even if the first is correct, incorrect or subsidized actuarial point of view is likely to continue insurance under reduced dramatically since the probability of loss decreases and loss probability increases, keeping constant the expected loss.

The most popular theory of decision, expected utility theory predicts a much insurance and contradicts all the axioms postulated in above. For example, a risk averse decision maker will buy full insurance if the premium is actuarially correct. In contrast, Kunreuther (, Insurance decision making and market behavior, 2005) found that only 20% of some individuals in an experiment buy insurance at correctly calculated premium, if the probability of loss is 0.001. Moreover, rank-dependent utility and cumulative exploration theory was developed to provide better explanation of embedded risk behavior. There are probability weighing functions, one example being set by Prelec function to estimate probabilities (1998), which is consistent with the first axiom.

Kunreuther's study provides striking evidence regarding the purchase of insurance by individuals of inadequate insurance against events with low probabilities such as earthquakes, floods or hurricanes in areas exposed to these hazards. (Schoemaker, Kunreuther 1978)

Expected utility predicts that consumer will buy full insurance if the premium is actuarially fair in terms of all reported the following results probabilities. Kunreuther experiments presented various potential losses at different probabilities, keeping constant the expected value of the loss. Contracts included correct, incorrect and subsidized premiums, lead to the conclusion that in any case there is a point at which the subscription drops dramatically as the probability of loss decreases and the magnitude of the loss increases, keeping constant the expected loss. The potential insurance clients could be less aware of the losses involved in the process or could be subject to moral hazard. Lack of interest in buying an insurance remained active despite government attempts to: provide grants to counteract transaction costs, reduce premiums under actuarially fair rates, to provide reinsurance to companies or to provide relevant information. A good reason underlying insurance underwriting deficit is the lack of interest from the consumers. In different contexts, people ignore low probability events that can, in certain cases, to create a significant loss. Since many of these losses are imposed by consumers themselves because of individual actions, people choose not to insure. For example, people were reluctant to use their mandatory seat belts despite the evidence that they save lives. By 1985, only 10-20% of drivers wore seat belts, so denying their own safety.

## **2.The weak points of Expected Utility in explaining insurance behavior**

A major challenge is that individuals underinsure low probability events and overinsure moderate risks. For moderate risk they buy insurance with premiums that exceed the expected loss. Examples for this are demands for low deductibles, the markets for extended guarantees and insurances for mobile phones. Thus keeping the expected loss constant the insurance underwriting rate increases with the probability of loss. There is a standard expected utility theorem that says that individuals will fully insure if they have received the correct actuarial premium. Expected utility, gives a completely rational explanation of the phenomenon of underwriting. This has the implication that if the total provision is considered necessary, should be encouraged by subsidies or stimulated law. Expected utility is unable to explain certain insurance phenomena. First Kunreuther found that only 20% of subjects in the first experiment subscribe if the premium is fair and the probability of loss is 0.001. This theory was widely accepted and implemented as a descriptive model of economic behavior, as well as the model of rational choice, this means that the theory assumes that rational people would want to follow the theory axioms and, generally, they do this. Second, expected utility cannot explain why many people bet and ensure them simultaneously. The amount of gain or insurance makes it difficult to dismiss this behavior. Thirdly, the expected utility predicts that a risk averse decision maker will always buy insurance even if the premium is not equitable. However, many people do not buy insurance, even if they are available, especially for events with low probabilities. Fourthly, when first confronted with unfair premiums in terms of actuarial, expected utility predict that a decision maker is indifferent between full insurance and non-insurance and will prefer probabilistic insurance. Guilty for underwriting is a bimodal perception of risks which could provide an explanation in this sense. Some individuals focus more on probability, others do not pay attention to the loss. The first don't pay attention to the size of losses that fall below a certain threshold probability, while for last dimension of loss is relevant. Thus, the first are more likely to ignore insurance, while the latter ones buy for low probability but significant events. One of the problems is that the demand for insurance underwriting is determined by the loss, if the reference point is given by the initial wealth. Difficulties in the expected utility theory are raised by the emergence of a number of alternative for this theory. The most notable are rank dependent utility theory (Quiggin, 1982, 1993) and cumulative theory exploration. (Tversky and Kahneman, 1992). Unlike expected utility, the rank utility dependent theory of cumulative exploration functions are used for measuring the probability,  $w(p)$  to overestimate small probabilities and underestimate high probabilities. A function that is similar to  $w(p)$  which is consistent with many of the proofs of non-probability extreme events is the function of Prelec (1998).

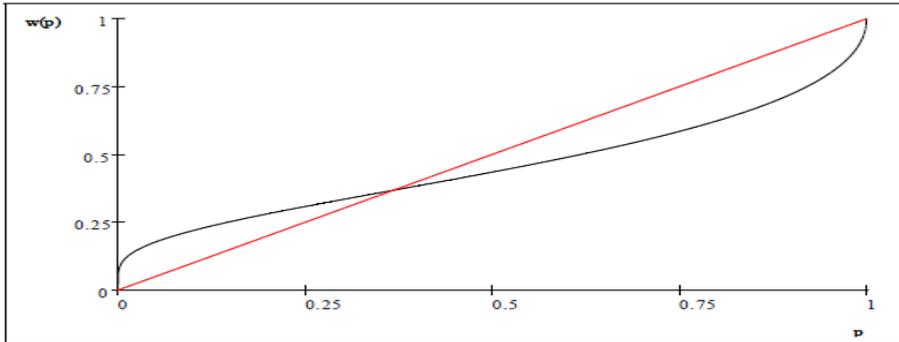

Fig.1.Prelec function

Source: :*"The behavioral economics of insurance"*, Ali-Al Nowaihi, Sanjit Dhami, University of Leicester

The decidents who use the rank dependent utility and cumulative prospect theory fully insure even in the case of a probabilistic low loss, in the case of an actuarial unfair premium and the fix cost of the insurance and if participation constraint is satisfied.

Utility theory rank and cumulative theory exploration could explain the above four axioms given that:

- during the editing phase, decision makers choose which improbable events to treat as impossible and which to treat as being sure. "because people are limited in their ability to understand and evaluate extreme probabilities, unlikely events are either ignored or overstated, and the difference between high probability and certainty is either neglected or exaggerated." (Kahneman și Tversky-Prospect Theory,1979:283)

- in the stage of decision / evaluation following that of publication, makers apply psychological theory lotteries already psychological editated.Choosing to ignore low probability events during the editing phase, decision makers do not require insurance for such events during decision-making.

- Axiom captures Prelec's function as the makers overestimate low probabilities and underestimate high probabilities, but invalidated by the second the small probabilities and large ignored deemed reliable.

- If you change heads and Prelec's function is considered as the editing phase of the evaluation were synchronized, the result will be composite Prelec's function

Those who use composite Prelec function will ignore low probability events by assigning subjective values to this.So, they will not buy insurance for low probability events unless are mandatory for a probability interval, policymakers overestimates the probabilities. Tversky and Kahneman cumulative theory introduced in addition to the Theory prospecting prospecting by completing the following: the psychological-editing phase which resulted, among other things, that events with small probability that are ignored should be eliminated.

Cumulative transformation of probabilities replaced the transformation point of Prospect Theory, a decision-maker who uses cumulative theory exploring options will never choose the dominant options in a stochastic manner.With other words, the

theory of cumulative prospect theory is nothing but prospect Theory complemented with composite function Prelec. Kunreuther argues otherwise: "The main reason for market failure is that most people do not use insurance as a means of risk transfer them to others, this behavior is caused by the refusal of people to worry about losses whose probability is below a certain threshold. "

The model that follows explain how the decision in insurance can be made when we have in consideration a certain loss and an interval of probabilities of (0,1). There are also put the conditions if the premium is fair or unfair and which are the effects of this fact upon the insurer's decision. In this context, it can be seen how Cumulative Theory define the utility and disutility function in this insurance context.

### 3. Model

Suppose that a decision maker may suffer a loss  $L > 0$ , with probability  $p$  belonging to  $(0,1)$  in these conditions can buy a cover  $C$  belonging to the interval  $[0, L]$ , at a cost  $rC + f$ , where  $r$  belongs  $(0,1)$  being first rate and  $f \geq 0$  fixed cost of insurance. (Ali-Al Nowaihi, Sanjit Dhami, 2010)

Insurance premium rate  $r$  is:  $r = (1 + \theta)p$  where  $\theta = 0$  corresponds  $p$ . Under fair actuarial and if  $\theta > 0$ , an incorrect actuarial conditions.

In other words, wealth maker is:  $W - rc - f$ , with probability  $p$

$W - rc - f - L + C \leq W - rc - f$ , with probability  $1 - p$

Let  $U_i(C)$  utility decision maker when deciding to buy a certain amount of insurance coverage,  $C > 0$ . Fie  $C^*$ , the optimal level of insurance coverage, Uni maker utility if he decides not to buy insurance, then decision maker who buys  $C^*$  satisfies the participation.

$$U_i \leq U_i(C^*)$$

The four main features of the theory of cumulative exploration (CP) are:

- In CP, unlike rank-dependent utility theory and the expected utility, utility determinants are the level of wealth, assets or property, but the difference between them and reference point. Reference point is usually, but not necessarily represented by status quo.

- the utility function is concave for gains exploring theory and convex for losses (decreasing sensitivity).

- disutility of loss is greater than the utility gain of the same size, it illustrates the loss aversion.

Probabilities are transformed so that small probabilities are overestimated but higher probabilities are underestimated. Considering the wealth level  $y$  and a reference point  $r$ , transformed variables  $x = y - r$ , where wealth is relative to the reference point.

CP utility function is defined on  $x$ ,  $x > 0$  is a gain when  $x < 0$  is a loss.

Utility function of CP,  $v(x)$  ( $-\infty, \infty$ ) is a continuous function, satisfying increasing reference point dependence  $v(0) = 0$ , decreasing sensitivity for gains  $v(x)$  is concave for  $x \geq 0$ , decreasing sensitivity loss  $v(x)$  is related to  $x \leq 0$  and aversion to loss- $v(-x) > v(x)$  for  $x > 0$ .

A popular utility function is axiomatic theory of cumulative exploration of the form:

$$v(x) = x^\alpha \lambda$$

$$- \lambda (-x)^{\beta} \lambda$$

The vast majority of the elements of this theory are important precedents, particularly through contributions of Markowitz (1952) and Allais (1953). Theory models exploring refers to choices that split the process into two stages: the first stage involves "editing" and the second phase involves "evaluation". Using an editing stage

is the most obvious feature of the PT. The second feature that distinguishes PT these theories is that the results are measured in terms of gain and loss relative to a certain reference point. In PT results are defined relative to a reference point that serves as "zero point" scale of values. It is often assumed in the analysis that the relevant reference point in assessing the gains and losses is the current wealth or welfare, but not always so. In particular, the relevant reference point can be expected status rather than current.

Expectations play an important role in the phenomenon of reference point. When people expect to receive a salary increase of 10%, for example, but receive only 5%, they tend to be disappointed. Their point of reference in this case is given by how much money currently receive, but as expects, so they encode and evaluate additional percentage of 5% as a loss rather than a gain.

Prospect theory complements other classical theories, especially the theory of expected utility in which the deviations from standard economic behavior are explained by introducing individual psychological mechanisms that explain consumer decision of the individual, such as aversion to loss function weighting decisions, framing effects, anchor effects, contrast effects or reference points .It wants to create an overview on consumer behavior especially in decision situations under risk and uncertainty.

In the table below, we can identify anomalies referred in Prospect Theory inconsistent with Expected Utility phenomena, phenomena involved and anomalies in accordance with the classification of belonging and Prospect Theory indicate those elements that are relevant to explain those anomalies.

<b>Phenomen</b>	<b>Domain</b>	<b>Description</b>	<b>Elements in PT</b>
Equity premium	Share market	Profitability of actions is too high in relation to the bonds	Loss aversion
Disposition effect	Share market	Keeping too long to actions that go to loss and resale of winning one	Loss aversion,reference point
Slope decreasing labor supply	Work economy	New York taxi drivers give up on working once they have reached the target	Loss aversion
Asymmetric elasticity to price	Consumer goods	Purchase is more sensitive to price increases than to decrease	Loss aversion
Insensitivity to bad news concerning incomes	Macroeconomy	Consumers decrease their consumption	Loss aversion, reference point

displacements of „status qvo” and „default”	Consumer’s choice	Consumers does not change health plans: choosing insurance that was before	Loss aversion
Effect “end of day”	Betting on horse racing	„Shift to long shots at the end of the day”	Reference point Depict marginal sensitivity
Favorite-long shot bias	Betting on horse racing	Favorites are under bet; „long shots” are over bet	Estimating the decision: overestimate low probabilities
Buying insurance by fax	Insurance	Consumers buy insurance at inflation prices	Estimating the decision: overestimate low probabilities
Loto demand	Loto bets	More tickets sold is as grand prize grows	Estimating the decision: overestimate low probabilities

**Table 1** „Inconsistent phenomen with EU” Source: “An introduction to behavioral economics-a guide for students”, Nick Wilkison,p.87

Expected utility theory is also difficult when you have to explain the different attitudes we encounter relative to insurance. A buy insurance involves risk aversion, as they say in utility theory. However, the assumption that the utility function is concave in the area where is located the assets making utility theory to imply a universal attitude of risk aversion. This is in contradiction with the fact that many people prefer insurance policies offer limited coverage with low or no deductible, to policies that provide maximum coverage with high deductibles. So, buying insurance is in itself evidence of risk aversion, but some insurance policies that can be of great popularity, may be inclined to risk than others.

There is another phenomenon linked to insurance which seems to be an anomaly for both prospect Theory and for Expected Utility. This attitude towards the provision of probabilistic insurance. For this type of policy purchaser pays only a fraction of the price of full insurance, but only receives payment probability of the same fractions if the event occurs. It seems that such a policy involves more risk than standard insurance. Empirical evidence of Kahneman's study shows that such insurance are not popular, which seems to contradict the predictions of the model PT. This apparent anomaly of PT, with some tendencies towards risk taking in earnings can be explained only by a discussion of weighting decisions.

**Conclusions:**

-Prospect theory and Cumulative theory try to explain the consumer behavior in the insurance market taking into consideration the inconsistent phenomen of Expected utility theory in this context like: Insensitivity to bad news concerning incomes, elasticity of price, displacements of status-quo and default, disposition effect and equity premium.

-there are taking into consideration the aspects that Expected Utility theory cannot explain such as: decision makers overestimate low probabilities and underestimate high probabilities, decision makers tend to ignore very low probability events and cataloged events with very high probability of occurrence to be sure, the consumers buy inadequate insurance in spite of the low probabilities.

-even if the first is correct, incorrect or subsidized actuarial point of view is likely to continue insurance under reduced dramatically since the probability of loss decreases and loss probability increases, keeping constant the expected loss.

-cumulative transformation of probabilities comes as a transformation point of Prospect Theory, a decision-maker who uses cumulative theory exploring options will never choose the dominant options, the theory of cumulative prospect theory is nothing but Prospect Theory complemented with composite function Prelec.

- Prospect theory complements other classical theories, especially the theory of expected utility in which the deviations from standard economic behavior are explained by introducing individual psychological mechanisms that explain consumer decision of the individual, such as aversion to loss function weighting decisions, framing effects, anchor effects, contrast effects or reference points and Cumulative Prospect theory tries to explain why small probabilities are overestimated but higher probabilities are underestimated.

*maria.lacatus@dppd.ase.ro*

**Abstract:** *The main aim of the paper is to highlight the importance of financial and business education in the context of the more and more complex and dynamic economic and social systems specific to the modern societies. Financial literacy is a need for people responsible for the way money are managed in a competent way (both their money and other people money with a special dimension on the local/regional and macroeconomic levels). The decisions people made in respect with the money have impact on both short-term and mostly long-term future. Their responsibility and the risks assumed increase as long as employers and government responsibility and assumed risks in this respect might decrease in some cases. The paper is mostly design as a theoretical paper based on literature review and critical research and critical thinking methods. Based on the literature review the paper had identified the most important principles of financial education and illustrates some of these principles such as: active long life learning; oriented based mostly on individuals needs; connected with the early economic education provided both by formal education institutions (schools) and by non formal and informal training programmes like the one provided by NGO (such as Junior Achievement, CREE etc.) where basic concepts on financial issues have an important role; risks oriented. These principles and mostly the ways and forms to provide financial education both within a formal and non-formal framework are debatable subjects and critical thinking and comparative analyses might be fruitful into this respect. In Romania, financial education is in the majority cases part of the school based curriculum. The Ministry of Education recommends that all the educational institutions interested in delivering financial education programs within their schools have to develop also a syllabus for an optional subject that might focus on financial issues. Banks are also interested to contribute to the financial education. They might help schools in conducting financial education programs and, additionally, they developed their own financial education programs. Local and regional institutions are also very important and mostly from the long-run perspective they might make the difference for a sustainable development strategy where investment in life long learning economics, business and financial education have a crucial role.*

**Keywords:** economic education, financial education, financial literacy, competent money, school based curriculum, financial education programs.

## 1. Introduction

We consider that within a knowledge-based society and economy people do not have to look back to the economy of our childhood, but they have to be able to look forward to the economy of the future. Some authors may consider this statement challenging with respect to the financial education. But in fact financial education have to prepare people not just to register the performances obtained in the past (using complex financial and economic index). The financial education have to make people familiar with the expected evolution of future events when even the traditional concept of “money” will evolve and transform. *Competent money* will need people to be prepared to use money in a competent, effective and efficient way. And decision making with respect to money need not just a “reactive” way of thinking and behaving, but mostly an “anticipative” way to project the future, to take the proper decisions and to identify the most important expected consequences regarding how to use money in a competent way.

Within the modern society called the *new economy*, the *post-industrial economy*, the *creative economy*, the *knowledge-based society and economy* there is an important shift from the monetary flows towards the intangible one and from the physical and tangible assets towards intangible ones. Many of the new benchmarking methods are no longer applying just the monetary expression. Intangible assets and mostly intellectual (human, organizational, relational) capital are considered to be the real source of a long-run sustainable competitive advantage. More that 80 % of the value added of the “top” companies is extracting its value from the intangible assets. So this new framework addresses new challenges for economist and mostly for the financial sector and as an implicit consequence for financial and business education. Tacit knowledge, intellectual capital, knowledge management and other important endogenous source of a long-run sustainable development both on the micro-, mezzo- and macro-level are asking for a new paradigmatic thinking way with respect to money. New forms of money and new forms of trade and financial intermediation such as e-commerce, e-banking and many other new forms of exchange regard other perspective with respect to financial education. We need to need to encourage entrepreneurship, talent management and mostly the creative class to manifest in a creative way in accordance to the new perspective provided by the creative economy where the financial sector is also considered to be a special category of the creative industries.

Creative economy based on creative people, creative communities and innovative business are becoming relevant mostly during the amplified crisis. Some authors consider that crisis is the mother of invention and innovation. And many research studies had provided many examples of best practices with respect to the creative economy approach where the role of traditional money is changing in a significant way. New benchmarking like the *Global Innovation Index*, *Euro Creativity Index* or *KAM (Knowledge Assessment Method)* promoted by the World Bank rank countries performances no longer based just on GDP and other monetary index. Beyond GDP initiative adopted also on the European Union level in 2007 ask for an extension of the way we judge performance, efficiency, effectiveness and even rationality in the new economy context. Boundary rationality goes beyond traditional way of thinking. And it looks that we need a new way of thinking mostly if we want to face and to manage to realize the second part of the semantic meaning of crisis as a very challenging concept. We need even a new semantics where crisis does not mean

just damage. It regards mostly that people have to think in a positive constructive way and to realize that today crisis is very complex (moral, ethical, environment, demographic, economic, financial crisis co-exist and amplify their effects). As complexity science suggests, in order to cope with complexity we have to re-discover simple ways to deal with it. And mostly important we need to realize the second part of crisis semantics like in its old Chinese origin: opportunity to change something. This way of thinking applies also for money. In order to cope with the contemporary financial and economics issues we need a new paradigm with respect to money. And one of the most important ways to do this ask for a new paradigmatic perspective of financial education. Some of this new approach of the financial education as we manage to identify within the specialized literature are presented within this paper. Just some of them. We know that people use to look for mathematic, econometrics and statistical tools to be applied for scientific papers. But we consider that for emergent topics like the one we address before starting to apply a new /old econometric model we need to think in a new way. And this asks for a new way of thinking and acting in the context of new economy and knowledge-based society.

*Soft skills* are also important for financial education; mostly those that focus on problem solving, critical thinking, creativity, communication, team building. As suggested by Charles Lawton, chief economist for Planning Decisions Inc. in Maine *“the answer that emerges is that the model workplace of the 21st century is the Google playroom - a combination dorm lounge, cafeteria, artist studio, laboratory and playground. And the central skill is creativity-making connections and seeing the unknown, the perplexing, the out of order, the unexpected as challenging and fun. This new economic era will be far less dependent on geography and far more dependent on human ingenuity -a factor much more subject to our own public decisions”* (Lawton, 2013, p.2),

Lawton also suggests that the new monetary flows have to take much more into account the unique and original goods and services according to individual needs and not to the mass production like in the industrialized era: *„The last century was about standardization and mass production. The next is about individualization - of both product and production. Google's business model for its glasses-embedded computer is to give thousands away and ask people to find cool things to do with it. Instead of centralized control, the goal is crowd-sourced direction”* (Lawton, 2013, p.3).

The recent economic crisis emphasized how important is for individuals and families to have information, competences and adequate tools for making good decisions in a financial system that becomes more and more complex. The crisis showed that individual financial welfare is fundamental for financial stability at national level and that a poor financial education is one of the reasons for decrease in standard of living and prosperity. The weakness and difficulties face in order to promote a proper financial education in line with the new approach we highlighted before makes difficult for people to be informed participants in economic activities. This is the main reason that explains why financial education became a priority in European Union. As an additional argument we mention that in 2007, *European Commission* adopted *Communication COM (2007) 808*, that established basic principles in financial education programs that are presented briefly within the following paragraph.

## **2. EU principles for high quality financial education**

Based on pertinent analysis of existing financial education programs in EU, EU Commission established basic principles to help public authorities, suppliers of financial services, consumers organizations, employers, and other entities interested in conducting financial education programs at local or national level. These principles are consistent with nowadays approaches and methods designed in order to develop successful financial education strategies.

*Principle 1: Financial education has to be actively promoted as part of lifelong learning process.* Financial education programs have to be designed for youngsters and elderly as well and to empower people to face financial challenges they experience in their everyday life. Financial education programs have to be adapted to citizens' financial situation and understanding.

*Principle 2: Financial education programs have to be clearly oriented to people needs.* Achieving this objective depends on research conducted to identify the present level of financial knowledge individuals have and also the concepts, issues, and problems that need to be immediately studied. Financial education programs have to be available in time and accessible as well. They have to target people in specific situations and with specific needs: graduates searching for jobs, unemployed people, couples who want to become families, youngsters, people who want to borrow money and so on.

Accessibility is especially important in order to facilitate people access to information. Accessibility is a requirement for content (the information) and content format as well. Financial education can be delivered in schools or out of the school; it can be part of formal or non-formal education. Adult's financial education can be delivered also in partnerships with employers; it can be delivered at work places and may be focused on pension systems.

*Principle 3: Economic and financial education has to start as early as possible.* Financial education has to be part of school curriculum. In other words, schools have to provide financial education to students. It is important that financial education start as early as possible, even in elementary school. EU Commission has published a recommendation regarding key-competences in lifelong learning process (2006/962/CE) that advocates in favor of basic competences such as capacity to apply mathematical thinking in daily life situations, to understand deeper the economic mechanisms, or to plan and to organize your personal life. The recommendation explicitly asks educational authorities to support and promote economic and financial education.

*Principle 4: Financial education programs must create awareness to the need of financial information and financial risk understanding.* Consumers are not always aware of lack of information they have in respect with financial issues and risks. Making them aware is the first step to positively motivate people for financial education. Instruments such as self-assessment questionnaires or commercials for financial education may help to increase the level of people awareness. Informed people can be oriented to specific financial themes and issues.

*Principle 5: Financial education has to be balanced, transparent, and objective. Consumers' interests are always priorities.* Financial services sector has to be involved in financial education. Employers in this sector have to be encouraged to

take initiatives and to contribute to financial education with their valuable expertise. Financial services providers should make clear differences between general and financial education and financial counseling, and this has to be also clearly presented in educational materials developed.

*Principle 6: There should be available resources for effective financial education programs and trainers in this domain should be properly trained.*

In order to have effective financial education, the trainers who conduct such programs should be well prepared and trained. This is true not only for teachers in schools, but also for social assistants, banks employees, volunteers and all other categories of educators that act in public benefit. As consequence, training of trainers programs has to be designed and educational materials to be developed and adapted.

*Principle 7: At national level, all interested entities in financial education have to be involved. Roles have to be clearly defined so that experiences to be shared, and resource to be rational allocated.*

*International cooperation between financial education providers has to be enforced so that best international practices to be shared too.* There is no monopoly on financial education. Many entities work together to educate people in financial domain: school, financial services suppliers, consumers' organizations, family and other interested parties. This contributes to establish more clear objectives, target better specific groups, allocate more rational the resources, and to promote experiential learning. At international level, cooperation between financial education providers and establishing financial education networks would help identifying domain that need special attention and sharing best practices.

*Principle 8: Financial education providers periodically have to evaluate their programs and, if necessary, adapt them to the best practice identified.* Financial education providers periodically have to evaluate progress and results. If necessary, they have to make changes in their programs to achieve the highest standards existing in the domain. Consumers have to have access to specialized information that may guide them through complexity and diversity of financial services.

### **3. The role of financial educational programs in school and other educational institutions in the context of formal versus non-formal and informal life long learning**

Experts agreed many years ago that in Romania financial education in a need. There is consensus in recognizing that economic and financial education helps youngsters to a better management of personal finances. Young people who have developed an economic way of thinking are self-confident, capable to make better financial or carrier decisions and to act responsible as informed citizens. Financial educational is based on basic economic concepts and economic way of thinking and is designed as an authentic program of financial literacy.

*Financial education*, both for middle and high school level, is an optional subject proposed and approved by the Ministry of Education. It was proposed on the recommendation of *the European Parliament and EU Council* as a subject that can develop *key competences related to long life learning capabilities*. On the European Union level experts and decision makers suggest that each person must have, and also skills student must have, including: initiative, social and civic skills, or learning to learn.

Financial education is part of school based curriculum. Its objectives can be achieved by interdisciplinary approaches within the *Civic Education/Culture*, or other *Humanities* disciplines, namely the social sciences curricula. It has been taught, actually learned, since the school year 2011-2012.

The existence of a discipline that addresses the relationship between consumer characteristics and consumption was considered extremely useful, taking into account that Romania is one of the European Union countries where consumption is too high. Often, this was highlighted during the boom, when Romania's economic growth was based mainly on consumption and real estate sector growth that has been proved not being sustainable.

Conducting financial education programs in schools might leads to the development of skills/ competences such as: learning the main notions of consumption, and consumer behavior; ability of rational management the financial resources; ability of correct management of the personal budget or family budget out of which the student comes from; developing an active and responsible social behavior, adapted to economies in transition, rapidly changing; developing the spirit of saving, meaning that students should avoid excessive consumption behavior based on it would have certain skills that can make the difference between what is necessary and what is extra; cooperation with others to solve problems of economic, social, theoretical or practical nature which may arise in the community or in different groups in which the individual carries out its activity/ business. Therefore, financial education would create rational and informed consumer behavior related also to the economic characteristics of the environment in which they live.

Financial education focuses on recognizing the quality of goods and services, on ability to draw up a personal budget, effective allocation of financial resources and the decision made in respect with appropriate banking products and lifestyle habits. Because of these issues, it is considered that possession of such knowledge is essential in understanding how individuals act and how interdependent relationship between individual behavior and the economy taken as a whole are created. Financial education programs are developed traditionally around some basic economic concepts such as: money, incomes, consumption and savings (Tables 1 and 2).

Thus, first, there is a continuity of concepts acquired, a more detailed study of the passing of their secondary education at school. This is justified not only by mastering the basics in high school, but also a greater capacity for analysis and perception of the phenomena studied and their implementation in everyday life. In this respect, the main content Gymnasiums education is based on the concept of consumer, on the family budget, on how the financial needs can be met immediately or postponed by means savings or taking out a bank loan and the benefits and risks arising in relation to consumer-financial institution. To this, add other content, in the second stage of deepening that matter, the most important being how to use banking services (deposit, credit card, electronic bill payment partner services), awareness of ensure personal and property ownership and matters related to *the National Bank* and Romania to the euro changeover conditions.

Source: Romanian Ministry of Education, 2010

Financial education is considered by many teachers of economics a 'weaker' form of economic education, meaning that just about some basic economic concepts and summarized in a basic level of analysis. Calling over the terms of everyday speech and, if possible, to limit the use of specialized language.

We consider that in order to promote a competent financial education educational programs need to be conducted not only by formal education institutions but also by the banks and non-governmental organizations

The issues outlined above, have resulted largely in theoretical characteristics of the subject of financial education. However, not only at the secondary education this approach there, but it is embodied in the various programs implemented by banking institutions or insurance companies. In this regard, recall the CSR policy of these institutions, which aims to inform citizens about certain features. Currently, programs targets young people from universities and colleges, in an attempt to support financial management and assimilation characteristics of products and services banking. The programs also advise anyone wishing to know deal with how to achieve a budget or how to use certain banking instruments. Other programs provide information about life insurance and about the financial planning.

#### **4. Conclusions**

Financial education is based on principles such as: active long life learning, individuals needs oriented, part of the early education provided by schools, basic concepts on financial issues and risks oriented. In Romania, financial education is part of school based curriculum. The Ministry of Education recommends all schools interested in delivering financial education programs schools a syllabus for an optional subject focused on financial issues. Banks are also interested to contribute to financial education.

Within other papers we provided additional practical evidence of the performances obtained by one of the non-governmental organizations where both authors of this paper are involved-CREE (*Centrul Roman de Educatie Economica-Romanian Centre for Economic Education*). CREE had been created in 2001 with the support of NCEE (*The National Centre for Economic Education from United States of America*) where both authors had benefit on two programs dedicated for "Training of trainers" and corresponding for "Trainers of Writers". This paper tries to support a new paradigmatic way of thinking. So we were not intending to provide a collection of data, econometric models, equations, regressions, graphs and other tools used by empirical studies. We applied these tools for other research. But the main purpose of this paper was to review the most relevant studies identified within the specialized literature and to try to ask first experts in the economics and finance research fields to debate these new approaches. Next, in a co-operation spirit we can develop also a more pragmatic vision and come with concrete results. We wanted first to benefit on the opportunities provided by participating to scientific events like the prestigious International Conference organized by our colleagues from the *Faculty of Economic Sciences from University of Oradea*.

Future research could be oriented to improve and to develop appropriately the present financial education curriculum. Specific content and methods could be developed, teachers guide and students centered materials could be developed. Both students and teachers would benefit.

# THE ECONOMY IN BIHOR COUNTY IN THE CONTEXT OF THE GLOBAL FINANCIAL AND ECONOMIC CRISIS

**Ștefănescu Florica, Bekesi Delia**

*Department of Sociology, Social Work and Philosophy, Faculty of Social Sciences, University of Oradea, Oradea, Romania*

*florica.stefanescu@gmail.com*

*georgianabekesi@yahoo.com*

**Abstract:** *This paper proposes an approach of the relationship local-global in terms of the response of local economy to the challenges of the present economic and financial crisis. We reviewed some ideas from the specialty literature on the topic of the paper and we developed a case study on Bihor economy. We proposed to check to what extent the local economy has relevance in a globalized world. For this purpose we used the method of studying documents and we realized a comparative study of national and economic development in Bihor during the financial and economic crisis (2008-2011).*

*The analysis of socio-economic indicators for the period 2008-2011 in Bihor county shows a specific response of Bihor economy to the economic crisis, arising from the particular conditions that characterize this area. Even if there are elements of convergence with the general features of the global crisis, there are a number of features that enable a rethinking of the role of the local, of communities in future economic developments. Taking into account the economic and demographic particularities of Bihor county, the local authorities have developed strategies that enabled a superior utilization of local potential and the reduction of vulnerabilities.*

*Thus, in order to attract local and foreign investors, a network of industrial parks has been developed, along with providing facilities to potential investors. Located in the border area, Bihor county benefited from European funding opportunities specific to these areas, in this case HU-RO, which involved joint projects with the Hungarian areas bordering Romania, which were heavily accessed with visible results especially in the plan of SMEs, infrastructure, culture, education and health. Special attention was paid to energetic strategy as Bihor County has significant geothermal resources. Being a multi-ethnic and multi-religious county, a cultural strategy was considered appropriate, having as main objective the increase of quality, diversity, attractiveness of cultural life, intercultural support, stimulation of cultural performance, and the maintenance and restoration of cultural sites. Another strategy was developed in tourism marketing, as the tourism potential of the county is high, but poorly capitalized because of road, rail and air infrastructure, which is more precarious than in most areas of the country. The conclusions of the paper favor the idea of decentralization encouragement which allows greater flexibility and adaptation to "the present time", especially in terms of policies and strategies that can be shaped and implemented.*

## **Introduction**

Even though we live in an increasingly globalized world, or maybe that's the reason why, the local or regional not only do not lose their functions and importance, but even reinforce them. Despite the growing and increasingly strong interdependencies among national economies that generate a certain uniformity of content, of response to similar situations, the regions continue to present a multitude of specificities deriving from the geographical or geostrategic location, environmental factors, economic and demographic structure, social and cultural capital.

An approach of the local economy in the context of a global economy can seem a superfluous approach, like "a drop of water in an ocean." At a closer glance, however, things are quite different, for at least two reasons: the local economy is more important to the community than the global economy, a fact suggested by Castells (2000a) when stating that only "elites are cosmopolitan, people are local" (Castells, 2000a:446); economic interactions are nowadays so numerous and complex that they justify such an approach. In addition, "global society is currently on an unsustainable path" (Mohareb, Murray, Ogbuagu, 2009: 1), as long as the need for raw materials, per capita consumption and population growth exceed the limits of sustainability.

The current economic and financial crisis reveals the presence of an autoimmune disease in the body of the global economy. A latent disease that has erupted when the loans have exceeded any limit, when "bubbles" in real estate began to burst, when the banks, amid some deregulations, so with the complicity of Governments, have excessively produced much play money, creating the illusion that money itself produces value, when banking imposed dictatorship. A disease favored by the out of control activity of TNCs and, even more sadly, by the involvement of scientists in the creation and development of speculative activities. The treatment, difficult to be prescribed, relied mainly on "drugs" discovered by Keynes as being effective in the case of the great depression of 1929-1933: a mixture of public policies that reduce taxation and budgetary spending and stimulate consumption

However, is it the same disease or are symptoms the same? Even if we admit that we're talking about the same pathology, the patient is a different one and requires a specific treatment. On the other hand, different forms of manifestation, like the different impact of the crises require specific measures for each country: United Kingdom stimulates employment, France supports those with low-incomes, Germany stimulates the renewal of the auto-park, Slovakia encourages part-time jobs instead of redundancies, Russia finances the interests of loans, Norway reduces taxation, Japan counts on green energy. Different measures that they have a common denominator: State intervention.

Paul Krugman, the winner of Nobel Prize for Economics in 2008, pleads for the rapid and massive intervention of the State to reinstate lending and boost expenses in order to overcome the decline in confidence in the banking system, as well as for a more careful regulation of banking activity, of stopping "shadow banking", warning in the book with the same title, on the return of "decline economy". Only the State, he argues has the necessary levers to prevent the appearance of "speculative bubbles" in economy, either financial, stock or real estate ones, which break eventually, with repercussions such as: the decline in investments, consumption, general demand, increased unemployment, declined living standards. (Krugman, 2009: 79, 173-175).

### ***Global and local in the contemporary world***

Systematized in the surprising expression that the world is a "global village" (McLuhan, 1962), globalization has emerged as a defining characteristic of the contemporary world, consisting of a wider process of integrating systems: economic, cultural, political, social, communicational, situation in which numerous works in various fields privilege the global at the expense of the local. Defined as an "intensification of worldwide social relations, which connect distant locations so that local happenings are shaped by events that occur many miles away and vice versa" (Giddens, 1990: 64), globalization has more an anomic nature rather than an organized, homogeneous one, which can generate a "clash of civilizations" (Huntington, 1998).

Although the globalization process began in the fifteenth century (Waters, 2001), we talk about it especially at the end of the 20<sup>th</sup> century, at the same time with the amplification of the phenomena that characterize it: relocation, movement and acceleration, standardization, interconnection, enhanced vulnerability (Eriksen, 2007). Unlike previous centuries, today globalization acquires, along with the economic dimension (meaning convergence of markets worldwide, accelerated capital flows, which escaped state control, transcend national borders) and a cultural and political dimension (Held et al. 2004), environmental, physical and mental dimension, amid the disappearance of trade barriers, mobility, communication, dissemination of information, the establishment and functioning of international institutions, of spatial and temporal barriers.

Globalization can be highlighted by means of several indicators such as: trade volume among the countries of the world, international mobility, capital flows, the number of Internet connections. These indicators, and many others that capture the phenomenon of globalization, have grown spectacularly in recent decades, which entitles the claim that "there is no old cartography. It has become an illusion" (Ohmae, 1995: 20) or "the end of geography" (O'Brien, 1992), meaning border permeability and penetrability.

An approach of the actual world in its complexity, can lead us to the conclusion that the levels: global, national or local, or as Manuel Castells said, "the space of flows" - abstract from social, cultural, historical point of view, and "the space of places" - which condenses human history and material culture (Castells, 1990: 14), coexist and intersect in contemporary society, that "the work process is globally integrated, but labor tends to be locally fragmented" (Castells, 2000b: 18). Hence the terms "fragnegration" (Rosenau, 1994) or "glocalization" (Robertson, 1995) that suggest, along with the phenomenon of homogenization, of interdependence, or even of response to these phenomena, that there is a process of reconstruction of the local, of retrieval and expression of identity.

There are even opinions that argue that regionalization, not globalization, is the element of the age (Czempiel, 1999) or that "globalization has gone too far" (Rodrik, 1997), that there are global problems (crisis, pollution, inequality etc.), while the solutions are mostly local, after the formula "think globally, act locally". It is an idea that is found in the work of Lester Brown (Brown, 2006: 286) who considers that "saving the planet" depends on the involvement of each of us.

The local is "internal, close, familiar, even intimate" (Bauman, 1998), determined in space and time, it gives identity and preserves traditions, it generates a sense of familiarity and safety. Moreover, it can be said that any manifestation of globalization "always has a local root, a particular cultural insertion, and, even if it is often spoken

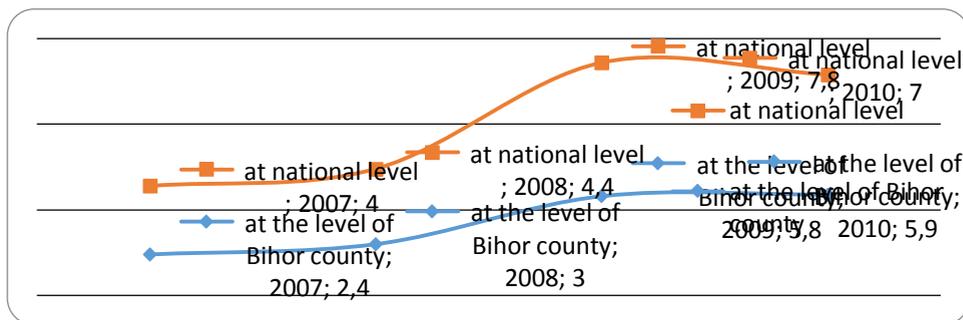

about relocation and deterritorialization caused by global changes, we must also consider that every movement is followed by a new rooting, a reterritorialization in another context "( Dimitrova, 2005: 6).

In other words, the local is not less important than the global, the two realities coexist, are complementary, situation expressed by terms such as: globalized localism (i.e. globalization of a local phenomenon) or localized globalism (meaning the local impact of a global phenomenon).

**The evolution of economy in Bihor county in the period 2007-2011. Similarities and specificities in relation to global economy**

With an area of 7544 km<sup>2</sup>, or 3.2% of the country and with a population of 594,615 inhabitants (2.76% of the population of Romania), Bihor county, located in the country's western border, as well as other counties in the same situation (Satu Mare, Arad, Timiș), has a number of specificities derived from its presence in the border area. One can talk about a higher purchasing power in the case of many of its inhabitants because of the opportunities to take advantage of leu-forint exchange rate and the prices in the neighboring country at certain times. Simultaneously, Oradea develops as a commercial city, the retail sales volumes increasing due to purchasers from the neighboring country. This situation is facilitated by short distances and by the lack of language barriers, as in the border area both languages are known, by both sides, at a level that allows individual trade and not only. In recent years demographic changes have intensified, it's true, mainly from east to west, from Romania to Hungary. Many Romanian citizens of Hungarian nationality sought and acquired the neighboring country's citizenship and, along with it, a series of accompanying rights, including the right to receive a pension granted by the Hungarian state based on the protocols between the two countries. A number of citizens from the border area, regardless of ethnicity have purchased homes and land in Hungary in favorable conditions both in terms of price and of infrastructure of localities, due to population migration in Hungary from east to west.

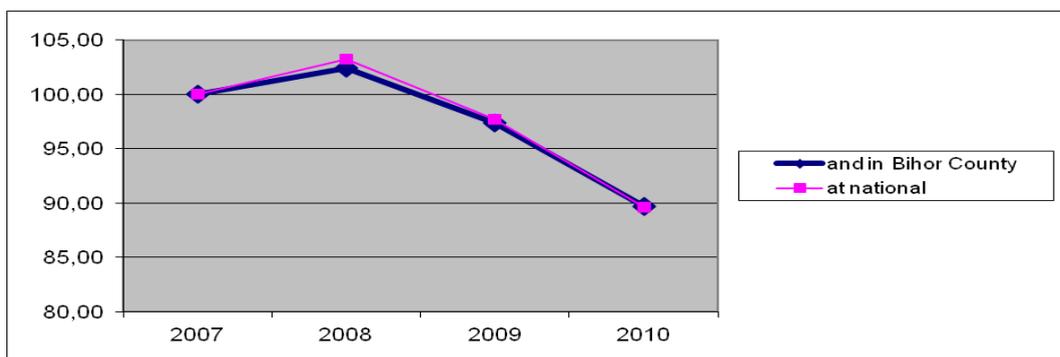

Also due to its geographical position, in addition to Bihor economic structure, we can talk about a relatively low unemployment rate (about half of the national average), and about fluctuations of local economic indicators compared to a predominantly linear-descendant evolution of the national ones.

**Figure 1.** Unemployment rate at national level and at the level of Bihor county  
Source: Romanian and Bihor county Statistical Yearbook

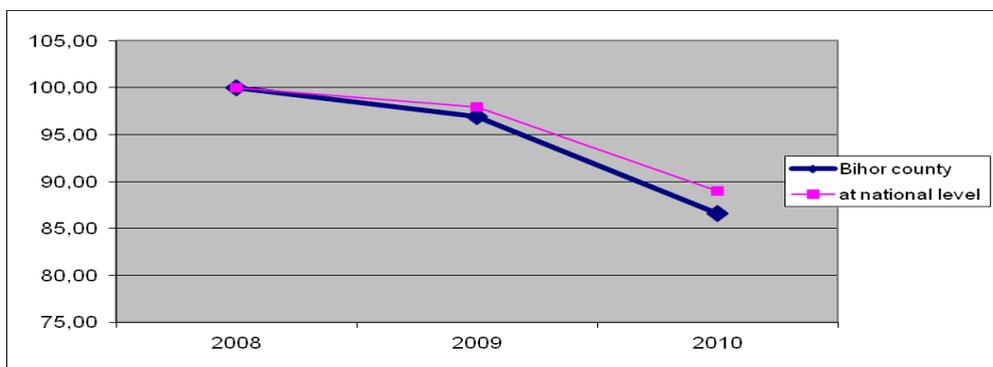

In these circumstances, the economic and financial crisis took on a slightly atypical form in Bihor county, it began to manifest only at the end of 2008, the early manifestations being related to production size restriction due to a decreased internal and external demand, increased unemployment and unemployment rate, decreased volume of international trade.

Industrial production, mainly concentrated in Oradea, is represented by: light industry, food industry, energy and machine construction industry, non-ferrous metallurgy - including mining, chemical industry, wood processing, construction materials industry. The diminished activity in industry was reflected in the average number of employees, which decreased steadily from 2008 to 2010, at the same time with the decreasing number of active local units (Figure 2,3) and the decrease with one-third of gross investment in these units in 2009 compared of 2008.

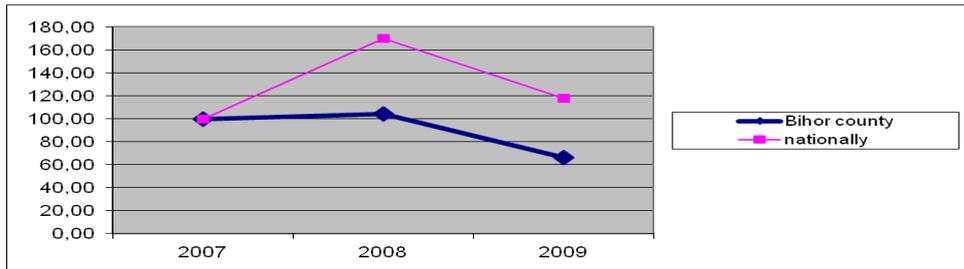

**Figure 2.** The evolution of the average number of employees nationally and in Bihor County (in%)

Source: Romanian and Bihor county Statistical Yearbook

**Figure 3.** The evolution of the number local active units at national level and in Bihor county (in %)

Source: Romanian and Bihor county Statistical Yearbook

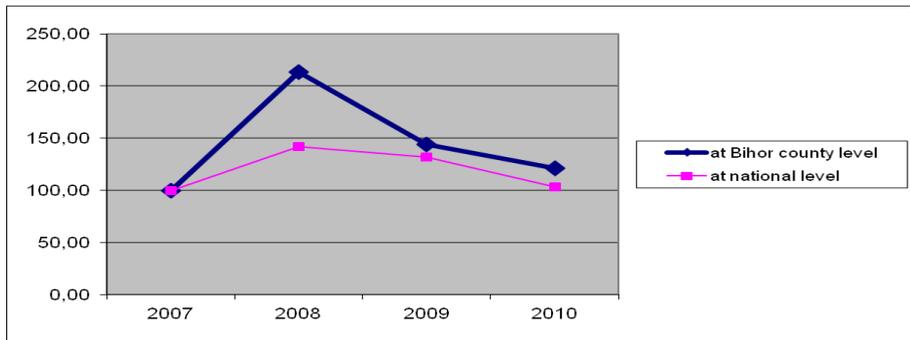

**Figure 4.** The evolution of gross investments in active local units, nationally and in Bihor county (in%)

Source: Romanian and Bihor county Statistical Yearbook

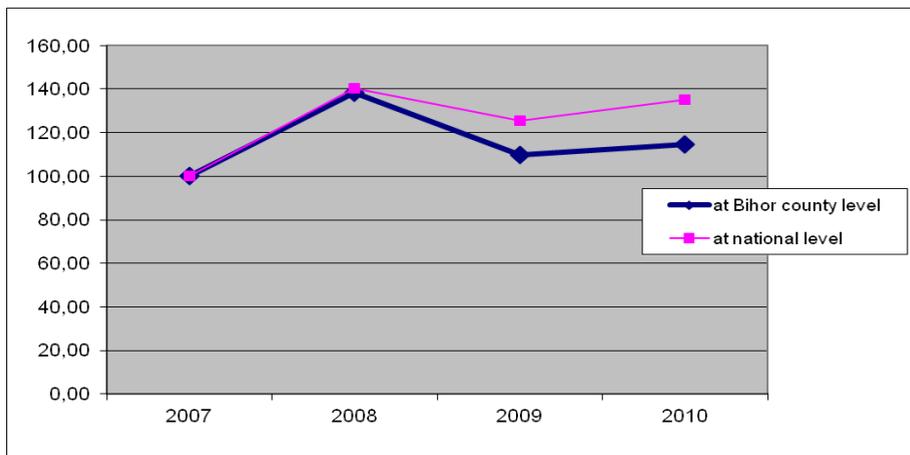

The figures above capture both "classic" and some particular relations, between situations and economic indicators. Thus, during the economic crisis some companies have temporarily or permanently ceased their activity in 2007-2009, while the remaining ones made larger investments in 2008 compared to 2007, after that the volume of investments decreased, which entailed an increase in the number of employees in 2008, followed by a steady decrease until 2010. However, we can see a difference in the evolution of economy at two levels: although the volume of investments (percentage) increased much more nationally than in Bihor county in 2008, the evolution of the average number of employees is similar. The conclusion concerns the efficiency of investment, much higher in Bihor county than the national average. It is an evidence of how the opportunities related to the local can be identified.

Not all industry branches are equally affected by the economic crisis. Some have followed the path of the global crisis, others have evolved in a specific way. In Bihor county, the first affected one was mechanical engineering (i.e. the parts for cars), but it has also been recovered first due to the "junk" program and the similar one in Germany that revived the domestic production of "Dacia" car. Construction followed, much later, and much less than in many other countries, probably because in Romania the construction boom occurred later. In Bihor county, even more than at national level, the number of completed dwellings increased greatly in 2008, then declined until 2010, but not below the level of 2007. The explanation could be seen on account of the return of many who work abroad and who have invested a portion of income in the construction of houses.

**Figure 5.** The evolution of the number of completed dwellings (in %) Source: Romanian and Bihor county Statistical Yearbook

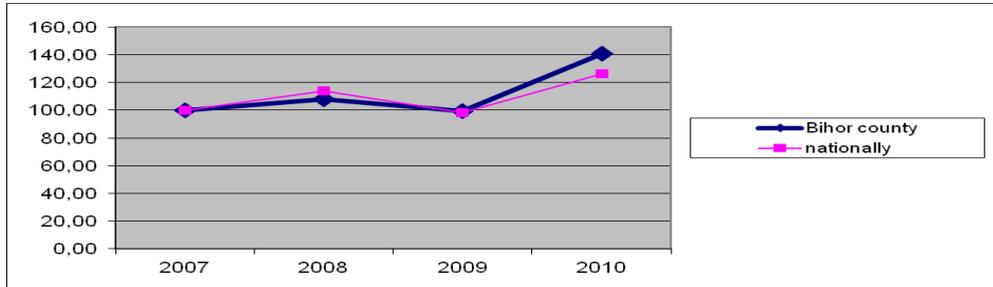

Regarding agriculture in Bihor, there are 497,167 ha of agricultural land, of which 3/4 is arable land (309,084 ha), of good quality, which favored the culture of cereals, Bihor county being ranked first in their production. Benefiting from large areas of pasture and meadows, and a tradition regarding livestock, this agricultural branch occupies an important share in the agriculture of the county. As a result, as well as at national level, the natural conditions favorable for agriculture, allowed an increase in the production of this economic sector, including a GDP growth from the results in agriculture, both in 2008 and 2010, as it can be seen in figure 6.

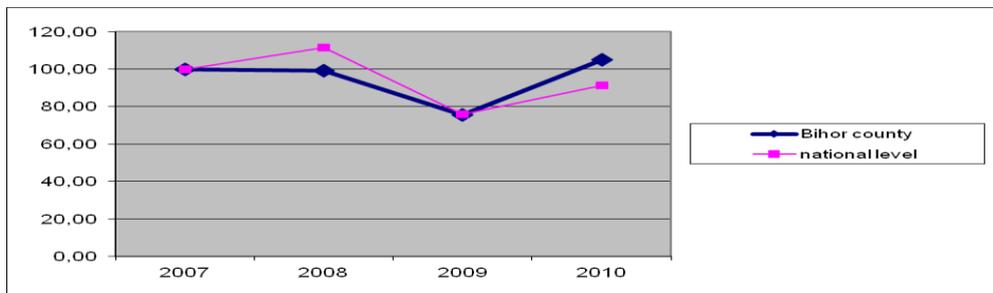

**Figure 6.** The evolution of agricultural production at national level and at the level of Bihor county Source: Romanian and Bihor county Statistical Yearbook

The economic crisis was felt in Bihor county also as a reduction in the volume and value of exterior trade, to a similar extent to the national development, drastically reducing imports in 2009, while maintaining a certain level of export, thus making it

possible to reduce the deficit of commercial balance. However, in Bihor county, an increase in 2010 of both imports and exports above the national average shows a more rapid and broader recovery of economy in relation to the national one as a whole. This can be attributed to Bihor economic structure, and also to the measures taken by local authorities to support the local economy.

**Figure 7.** The evolution of export FOB nationally and in Bihor County  
Source: Romanian and Bihor county Statistical Yearbook

**Figure 8.** The evolution of imports CIF (in%) at national level and in Bihor county  
Source: Romanian and Bihor county Statistical Yearbook

It can be said, based on the mentioned developments that, in the economy in Bihor, the economic crisis has some similarities with the general characteristics present at national or global level, but also some features embodied in a specific response, both of entrepreneurs and of local authorities.

### **Local anti-crisis measures**

The decrease of public confidence in state institutions, the more vivid presence in debates of ideas about "policy drift" (slip of public policy) as well as the increasing distance between political elites and citizens transfer to some extent the task of finding viable solutions to local administrations, which are closer to citizens, to their needs and possibilities.

Faced with manifestations of a profound, long and extremely complex economic crisis, local authorities were forced to assess the local impact of the crisis and to identify specific measures to overcome the difficulties yielded by this.

An EU survey on the responses of local administrations to the economic crisis (Anti-Crisis Policies in Regions and Cities Two Years On: public authorities working in partnership July 2011 Final Report) highlighted the concerns of public authorities and the solutions found by them to alleviate the impact of the crisis locally. Thus:

- A fifth of respondents said that the facilitation of attracting structural funds can be a useful measure in the crisis period (Anti-Crisis Policies..., 2011: 13)
- Half of them considered important to join efforts and information between local authorities and the private sector, especially SMEs (idem: 15)
- More than half rejected the assertion that "during the crisis it would have been a more active coordination of measures and exchange of information between cities/home regions and other cities/regions in the country or other countries (idem: 17)
- Concerning the attitude of local authorities in relation to the economic crisis, almost half of respondents said that the impact of the crisis on the local economy was evaluated, 71% said they had developed anti-crisis plans or local crisis monitoring (idem: 20-21)
- Only a third of respondents considered that local / regional needs can be found in the EU 2020 program (idem: 22)
- out of the anti-crisis measures adopted locally we can mention the following: financial support for SMEs, investments in research and development, measures to preserve existing jobs, measures to ensure the rapid (re) insertion in the labor market, measures to support the most vulnerable persons, measures to strengthen social protection and investments in social infrastructure and health, green investment, physical infrastructure, energy efficiency and the use of renewable energy, competitiveness of industrial base (idem: 23-26)

Taking into account the economic and demographic particularities of Bihor county, the local authorities have developed strategies that enabled a superior utilization of local potential and the reduction of vulnerabilities.

Thus, in order to attract local and foreign investors, a network of industrial parks has been developed, along with providing facilities to potential investors.

Located in the border area, Bihor county benefited from European funding opportunities specific to these areas, in this case HU-RO, which involved joint projects with the Hungarian areas bordering Romania, which were heavily accessed with visible results especially in the plan of SMEs, infrastructure, culture, education and health.

Special attention was paid to energetic strategy as Bihor County has significant geothermal resources.

Being a multi-ethnic and multi-religious county, a cultural strategy was considered appropriate, having as main objective the increase of quality, diversity, attractiveness of cultural life, intercultural support, stimulation of cultural performance, and the maintenance and restoration of cultural sites.

Another strategy was developed in tourism marketing, as the tourism potential of the county is high, but poorly capitalized because of road, rail and air infrastructure, which is more precarious than in most areas of the country.

## **Conclusions and discussions**

The analysis of socio-economic indicators in the period 2008-2011 for Bihor county reveals a specific response of Bihor economy to the economic crisis, deriving from the particular conditions that characterize this area. The geographical position (of border county), the economic structure of Bihor (diversified, well represented in all three sectors: agriculture, light industry, food industry, energy and construction machinery industry, non-ferrous metallurgy - including mining, chemical industry, construction material industry and services), strategies on activity fields (industrial, agricultural, energetic, cultural, touristic) have determined, along with similar developments at national or global level, specific developments, resulting in a better adaptation and restructuring of activity according to the conditions imposed by the economic and financial crisis.

Even if there are elements of convergence with the general features of the global crisis, there are a number of features that require a rethinking of the role of the local, of communities in future economic developments.

The anti-crisis measures taken locally and, especially, the chances of supporting them with desirable results for local economies, favor the idea of encouraging decentralization, thus enabling a greater flexibility and adaptation to "new times", especially in terms of the policies and strategies that can be defined and implemented.

## "NEW" AND "OLD" IN ECONOMIC NEOLIBERALISM

**Zirra Daniela**

*Department of Commerce, Integration and Business Administration, Domestic and International Commercial and Financial Banking Relations Faculty, Romanian-American University, Bucharest, Romania*

[daniela.zirra@gmail.com](mailto:daniela.zirra@gmail.com)

**Abstract:** *In the evolution of economic history, the economic neoliberalism can be considered one of the most important. On the one hand, neoliberalism is a promoter of freedom in decision making process and competition. On the other hand, the market and its capability to supply information for the individuals and firms represents one of the central pillars for economic growth, development and profitability. Finally, we cannot ignore the diversity of neoliberal ideas, the number of promoters, and the global extension of neoliberalism. For these reasons, we consider that a short incursion in the history of neoliberalism is also actual and necessary. In the recent evolution of the neoliberal doctrine we can mention several important stages in the 20<sup>th</sup> century. During the first stage – between the first and second decade - Mises revived the School of Vienna, in his attempts to combat the concepts strongly promoted in the economic theory by the socialist doctrine. The second stage, comprised between the third decade and the end of the fourth decade, was an unfavourable period, during which the concepts of liberal orientation were strongly criticized. The third stage of the neoliberalism evolution, as a doctrine, can be placed between the last part of the fourth decade and the end of the fifth decade, having as object of debate the criticizing of the concepts launched in the economic literature by John Maynard Keynes. The fourth stage meant the entry of neoliberalism in a shadow cone, which lasted from the beginning of the 1950's until towards the middle of the 1970's, due to the popularity "enjoyed" by keynesism. The failure to apply the keynesist theories, declared in the second half of the 1970's, meant the entry of neoliberalism in an extended stage of development, which lasted until towards the end of the first decade of the 21<sup>st</sup> century. After year 2008, there are voices stating that the neoliberal principles are unable to find the answer to the world economic crisis and that, in fact, their promotion to such a wide scale contributed to this negative evolution of the economy.*

**Keywords:** *economic thought; neoliberal paradigm; economic neoliberalism.*

**JEL classification:** *B13; B25; B53.*

### **1. General aspects regarding the development of contemporary neoliberal paradigm**

The first aspect to is the idea that neoliberalism has as basis the need to grant greater freedom to economic agents, in view of ensuring the conditions for achieving an efficiency level as high as possible in the current activity, although this freedom is reached by imposing a certain kind of limits (Braunstein & Pepin, 2000). For the neoliberals, competition represents the essential condition for ensuring real

economic freedom. In what concerns the state's role, the neoliberal theories show that one of the reasons for its existence is that of being an intervenient in protecting competitive relations, in view of ensuring the liberalism of the market relations. A central pillar of neoliberalism is constituted by the role of informatic system assigned to the market.

In this mission, the market must transmit the information from the consumer to the producer and vice-versa, such as information is decentralized to the level of each individual. Thus, the evolution of each economic agent, regardless of its dimensions, depends on the consumers' orientations and on the volume of goods and services purchased by them.

The understanding of the characteristics of contemporary neoliberalism requires the previous pointing out of some of the crucial moments which marked the theoretical and methodological development of the doctrine (Zirra, 2013). The first of them, and probably the most important, is year 1938. Then was held the meeting of the Walter Lippmann Colloquium, after which in 1936 was published the Keynes's work, *The General Theory of Employment, Interest and Money* (Nica, 1997).

The ideas promoted in year 1938 were resumed in 1947. On the date of April 8<sup>th</sup>, in Mont-Pellerin was held the reunion of several Western specialists, from different fields, as a result of the initiative of three great personalities of that period, respectively Friederich A. Hayek, Ludwig von Mises and Wilhelm Röpke.

Throughout the evolution of neoliberalism, different Schools and economic theories were sketched, which were enriched as this doctrine won new adepts. German neoliberalism, or ORDO-liberalism, was promoted within the Freiburg School, created by Walter Eucken. Among the representatives are Franz Böhm, Ludwig Erhard, Wilhelm Röpke, etc. The representatives of this School were promoters of market social economy. The School of Vienna, also called the Austrian School, was another strong European centre within which neoliberalism manifested and developed. Carl Menger was the creator of this school, in the second half of the 19<sup>th</sup> century.

Together with Carl Menger, Friederich Hayek and Ludwig Mises are two renowned representatives of the Austrian current, thanks to whom intransigent liberalism subsequently became the main trait of neoliberalism. In the United States of America, the neo-classical theory was revived towards the end of the 1950's, being associated with the re-emergence of the liberal doctrine, due to the economists within the Chicago School, established by Frank Knight during the inter-war period (Hausman, [1984] 1993). Subsequently, the Chicago School was lead by Milton Friedman and Herbert Alexander Simons, among the promoters being also Hayek. As can be seen, the diversity of ideas of neoliberal orientation is great. For this reason, is necessary a clarification of the concepts of neoliberal origin, such as hereinafter we shall refer to several of the contributions, we believe, representative for the theoretical and methodological development of contemporary neoliberalism.

## **2. The main contributions of "old" neoliberalism**

Friederich Augustus von Hayek (1899-1992), eminent representative of the Modern Austrian School, studied under the coordination of Friederich von Wieser, being a colleague and protégé of Ludwig von Mises. Hayek had an immense contribution to the popularization of Austrian neoliberalism within the Anglo-Saxon countries (Klein, 1999). Hayek's first concern has as initial impulse his desire to contribute to Austria's social and economic development, which, due to the world events, had reached a

condition of accentuated poverty. In these conditions, Hayek's leaning towards the socialist orientation current, which has become very visible during that period, may be considered natural. In a second stage, Hayek started from one of the theories launched by Mises in the *Theory of Money and Credit* (1912), according to which the value of money is subjected to the theory of marginal utility, same as the value of any economic good. On this basis, Mises elaborated a theory of economic fluctuations, specific to the field of industrial production.

At the beginning of the Second World War, together with many of the Austrian School's representatives, Hayek left Vienna, becoming in 1931 leading professor of economics and statistic within the London School of Economics. From this position, criticizing the *Treatise on Money* of John Maynard Keynes, Hayek appreciated that his theoretical and methodological efforts to promote an inflation-reducing strategy were laudable, in spite of the fact that he did not agree the theories promoted by his contemporary fellow. In 1950, Hayek joined the representatives of the Chicago University, within which was functioning the so-called Committee on Social Thought. We must mention that during the starting period of the 1950's, in a context more than favourable to the development of the keynesist doctrine, neoliberalism entered a 20-year long period of „hibernation“. The moment that many consider especially important for the revival of the neoliberal paradigm is that when F. A. Hayek became the Nobel Prize winner for Economics in year 1974. In the specialty literature it is considered that one of Hayek's most important contributions to the development of the economic thought is the *Theory of economic cycles*. In this area, the object of his interest was the relation existing between the fluctuations registered in the field of the work force occupation and of the production of economic goods, on the one hand, and the evolutions in the capital structure, on the other hand (Klein, 1999).

Having as basis the theories promoted by Böhm-Bawerk in the field of capital, Hayek shows that, in fact, the economic structure of production is directly determined by the characteristics of the capital goods, with reference to their characteristics regarding the substitution ability, complementarities, durability, etc. This idea was stated by Hayek in *The Pure Theory of Capital*, published in 1941 in Chicago.

Hayek was criticizing the Theory of general balance elaborated by L. Walras and W. Pareto, saying that an economic theory formalized from the mathematical viewpoint, as in the field of natural sciences, cannot be built (Beaud & Dostaler, p. 64), especially when it is a matter of such a difficult problem as the use of the work force. During the 1920's, he was influenced by the Swedish School.

According to Hayek, the market, as self-established order, results from the interaction between the individual economic agents and from the coordination of the information circulating among the economic agents, which are at the basis of their decisions. The fundamental elements of Hayek's conception are individualism and economic order. In his opinion, any worker of the individual order is not concerned only with the relative salary he expects from the different uses of his abilities and from the resources corresponding to the relative utility of the efforts made (Hayek, [1949] 1952).

In Hayek's vision, the prices system must be seen as a mechanism for communicating information, if the understanding of the manner of its functioning is desired. Hayek considers that only freedom allows the individual to pursue his own needs and to make optimum decisions in what concerns him. The fundament of freedom, in which distinctive personalities and ambient environments can be created, is private property (Hayek, 1988).

The concerns expressed by Wilhelm Röpke (1899-1966), regarding economic cycle, the criticism of Keynesism, national and international welfare, monopoly, economic theory and social theory, etc., gathered around the idea of rejecting the concept of collectivism in all its aspects, respectively in the economic, social, political etc. fields, in the light of the ethical fundamentals of the markets established on the basis of spontaneous order (Ritenour, 1999). Röpke was a defender of the principle according to which crises are not a product of free societies, but of state interventionism in different forms. In another order of ideas, Röpke was a renowned personality of the period following the Second World War, having an important role in influencing the strategic decisions regarding Germany's economic reform, as well as in the evolution of the American economic policy of conservative orientation.

Publishing in 1936 the volume *Crises and Cycles*, Röpke stated that economic cyclicity (Ritenour, 1999) has as first factor of influence the disturbances of the „process generating long-term investments”, respectively of the “industrial fields destined for producing capital goods”. In what concerns the attitude towards the Keynesist theory, Röpke criticized the concept of full occupation, indicating that the forced preservation of the interest rates at a low level, with the propagated purpose of increasing the occupation degree, can have no other consequence than the triggering of an accelerated inflationist process.

In 1947, together with Mises and Hayek, Röpke organized an international colloquium, to which he invited experts from different fields (economics, politics, sociology, philosophy, history etc.), for the declared purpose of consolidating the notion of freedom, in its different meanings. The result of this colloquium was the establishing of the *Mont-Pellerin Society*.

Another aspect clearly indicating Röpke's opposition towards the Keynesist theory is revealed in the volume *Economics of the Free Society*, published in 1963, also in Chicago. In this book, the author says that one of the most „harmful” ideas expressed by Keynes is that according to which the „economic system is part of a supra-mathematized mechanical device”.

To the same extent, Röpke manifested against the application of the Marshall Plan for the purpose of the economic reviving of Europe, deeply affected from the economic and social point of view by the unravelling of the Second World War. We cannot avoid mentioning that Röpke was also a contestator of monopoly. Defender and fervent promoter of the free market and society, he stated that large business, created in the name of increasing the efficiency of the economic activity, represent merely another form of collectivism and signify, in essence, the transfer of the economic decision to the centralized level. „Interventionism creates more problems than it solves”, said Röpke in *Economics of the Free Society* (1963).

Many voices state that, in fact, the so-called „economic miracle of Germany” after the war is due to Röpke's influence on Ludwig Erhard (Ritenour, 1999). Röpke himself affirmed that the evolution of the German economy was determined by the creation of specific infrastructure elements, of economic, social, political, administrative, legislative etc. nature, which ensured and, at the same time, favoured the harmonious development of market economy. In 1948, the monetary reform was performed in Germany, by means of the exceptional contribution of Ludwig Erhard.

### **3. What brings the "new" neoliberalism in economic theory?**

Exceptional journalist and renowned intellectual of last century, Henry Hazlitt (1894-1993) stood out in the evolution of the neoliberal economic thought (Tucker, 1999)

both by means of his great contribution to the popularization of Ludwig von Mises's work, and through his opinions regarding the theory of economic cycles. Subsequently, in the same spirit, Hazlitt manifested against what he called the „National Industrial Recovery Administration”, militating against all elements of keynesist nature, which had the destiny to give an impulse to the movement towards the health of the American national economy, strongly affected by crisis. Hazlitt's best known work, which made him very popular including among the economics passionate scholars of nowadays, is *Economics in One Lesson*, published in 1946 in New York. The ideas promoted by Hazlitt in this book and completely of neoliberal nature, the author being significantly influenced by the writings of his „mentor”, Ludwig von Mises.

In the long tradition of the Austrian School, Murray Newton Rothbard (1926-1995) enjoys a privileged position, for three reasons (Hoppe, 1999). First of all, he is considered the last representative of the mainstream current represented by the “old” Austrian School. Secondly, together with Mises, Rothbard is considered one of the most „comprehensive systems' creators”, as illustrated by his work *Man, Economy, and State: A Treatise on Economic Principles*, published in year 1962. Thirdly, Rothbard is considered „the last and most systematic representative of the Austrian political economics”. These ideas of Rothbard are stated in his work *Ethics of Liberty*, elaborated in 1982.

In what concerns Rothbard's contributions to the development of the economic theory, we will list, in a synthesized manner, several of them hereinafter. For start, we mention that one of the most important theories launched by Rothbard regards the concept of marginal utility. With respect to the theory of marginal utility, he brought valuable conceptual clarifications in the field. He said that any attempt of cardinal measurement of utility is senseless.

With respect to the concept of welfare economy, Rothbard ([1962] 1993) had a radical approach, reconstructing the entire theory on the basis of two concepts: individual freedom in what concerns the decisions targeting the assurance of the daily life and of human development (individualist self-ownership); individual preferences manifested or expressed within the market (demonstrated preference). The Chicago School was consolidated and stood out at the international level thanks to Milton Friedman's personality. The representatives of this school were against the increase of the state's role in economy, idea supported by neoliberals, even if it preponderantly referred to the protection of the free manifestation of competitive relations (Braunstein & Pepin, [1998] 2000). Friedman claimed the importance of the *market economy as support of the freedom of choice and of consumer sovereignty*. In the American neoliberalism framework different theories emerged, such as, for instance, the *Theory of the supply economy* and the *Theory of rational expectations*. Those who promoted the *Theory of the supply economy* were Arthur Laffer, Norman Ture, Martin Feldstein and Jude Winnicki. This theory highlights the negative effects that the controlling doctrine has on the American economy, which materialized in the discouragement of labour and investments, in the inhibition of private initiative, with serious results regarding the evolution of labour productivity (Sută–Selejan , 1997). The *Theory of rational expectations* separated from the monetarism of neoliberal nature. The promoter of this theory was John Fraser Muth, who launched the concept in an article published in 1961, with reference to the insurance market and the economic goods' market. The idea was subsequently taken over and developed by other economists, such as, for example, Robert Emerson Lucas, Thomas John

Sargent or Neil Wallace. They mainly referred to the fact that control is not capable to ensure development, prosperity and economic stability for large time horizons. Those who continued the American neoliberalism development, Mincer, Schultz, Becker and Stiegler, founded the *Theory of the human capital*. According to this theory, no wealth can be created without the contribution of human resources, which are considered a form of capital which can be administered after the same rules as the physical (material) resources.

As can be seen, the different aspects of neoliberalism show that there is no full coherence of the representative ideas for this doctrine. The specialty literature (Mudge, 2008) indicated that the moment when care neoliberalism was „officially internationalized” is year 1983, when in London was established the International Democratic Union. Among the renowned founding members of this Union, we mention Margaret Thatcher, George H. W. Bush, Jaques Chirac and Helmut Kohl.

#### **4. In conclusion**

In the current economic literature it is considered that globalization represents the peak of the neoliberal doctrine. This globalization of the economic policy is not entirely new. In 1920, the promoters of „economic liberalism” tried to reinstate the ambitions of the self-adjustment of the economic system, by eliminating the interventionist policies, which were interfering with the markets’ freedom. The negative consequences of this vision occurred in the immediately following period (1930-1940) and illustrated that the full liberalization of the market system is impossible.

In the 1960’s, the neoliberal doctrine diversified, new theories emerging (the *Theory of the rational expectations* and the *Theory of the supply economy*). Then, starting with the 1970’s, during the period of accentuation of the system crisis of the capitalist economy, several currents of „neoliberal orientation” emerged (the monetarist doctrine, the ultra-liberal doctrine, the libertarian doctrine), which started to offer both an explanation for the occurrence of the crisis, and a methodology for overcoming it. With the collapse of the Soviet system at the end of the 1980’s, neoliberalism occupied the centre of the political stage. The basic package of the policies promoted at present contains, in a first stage, the achievement of macro-economic stabilization, followed by the second stage of adjusting the market, in order for it to work efficiently. At present, it is considered that if the equitable development will continue to be left to the self-adjusting markets, the problem of inequity, of the occupation of the work force and of poverty, which currently manifest, will become more dramatic in the new millennium.

# **SOCIAL CAPITAL FRAMEWORK AND ITS INFLUENCE ON THE ENTREPRENEURIAL ACTIVITY**

**Badea Mihaela Raluca**

*Doctoral School of Business Administration, Bucharest University of Economic Studies, Romania*

*badearl@yahoo.com*

**Abstract:** *The aim of this article is to understand the theoretical framework of the social capital concept, based on different approaches identified in the literature and highlight the direct influence social capital has on the entrepreneurial personality characteristics of individuals and organizations. The objectives of the paper focus first on conceptualizing the notion of social capital, by acknowledging the social capital structure and components, the sources of social capital and its role in building social economy; further on, the article explores the influence of social capital in the creation of innovation and economic growth, its dimensions in the entrepreneurial process and the definition of the instruments of measurement, including indicators of trust-generalized and institutional, number of social networks, associational activities-passive and active membership and civic norms. The paper gathers some of the outcomes of different researches conducted in the literature with respect to the positive relationship between social capital dimensions and entrepreneurship, through attracting the right potential of human capital and the required level of financial capital, reducing the transaction costs, identifying new market opportunities and leveraging the social networks, transfer and knowledge overflow and information channels, enabling the launch and the survival of business venture and help gain competitive advantage that would ensure sustainability and success. The case studies referenced in this article use various approaches of highlighting the social capital as a key enabler and not necessarily a generator of entrepreneurial activity, by analyzing the likelihood to launch new ventures based on the interactions with key partners and exchange of information, the sustainability and success of a start up or push/pull factors that determine an entrepreneur to enter the new ventures environment. The article is concluded by a high level introspection on how social capital is created in large corporations, what are the dimensions and the structure of this new "must have" capital form.*

## **General Introduction**

In the context of a global, knowledge driven economy, the competitive advantage for becoming the leader in the organization, company or industry is not provided anymore by the level of physical capital possessed, but it is determined by strategic elements such as the individuals' knowledge; the goodwill and intellectual property and the number of social networks (Lakshmanan, 1994; Castells, 1998; Miller, 2005; Westlund, 2006). The mixture of these key ingredients becomes the recipe for success in the acceptance of Smilor and Wakelin (1990) who refer to it as the "smart infrastructure"; this connects the human resources and market potential, technology, capital and know how into one single element, similarly as pieces of a puzzle.

The paper is focused exclusively on discovering the first and the third element of this "smart infrastructure", namely the concept of individual knowledge- in this context how this can be shared and transferred through information channel and the one of

social networks and how can these be leveraged, in order to accelerate all the right components that enable an organization, either a new start up or a mature firm to perform entrepreneurial activities.

Since the framework of social capital is the one that covers both elements- the knowledge and information transfer and overflow and the social networks, I will begin by conceptualizing the notion of social capital, based on how this is defined in the literature, by identifying its structure and dimensions and its role in building social economy; further on, the article explores the influence of social capital in the creation of innovation and economic growth, its dimensions in the entrepreneurial process and the definition of key boosters, such as number of social networks, trust-generalized and institutional, associational activities-passive and active membership and civic norms. In order to highlight how social capital is given birth among the members of a community, the paper includes the outcomes of two researches conducted in the literature with respect to the positive relationship between social capital dimensions and entrepreneurship, through engaging the right potential of human capital, identifying new market opportunities and leveraging the social networks, transfer of knowledge overflow and information channel. The second part of the paper represents a high level introspection on how social capital is included in corporations' strategy, strongly connected with the three dimensions of social capital: structural, relational and cognitive. The last part of the paper covers the conclusions and the personal beliefs of the research conducted.

## **Methodology**

The methodology applied for writing the current paper is the literature review, by extracting some of the available studies and information that cover the influence of social capital on the entrepreneurial activity and the dimensions of social capital in organizations. As I am trying to put in place the general framework for social capital and its impacts on the entrepreneurship in general, in order to identify the most relevant articles, I looked for the papers having in the subject name key terms related to the topic of my paper, such as "entrepreneurship" "new start ups", "innovation", "new business", all of them in correlation with the social capital concept. Even if references for social capital framework include writings from the 90's, most of the studies covering the roles of social capital in organizations and its influence on the entrepreneurship were conducted after year 2000, reason for which I chose to include outcomes of two studies performed in 2008, consequently 2011, that I found relevant for the topic selected. The general scope of the paper is to understand the background of social capital concept, in relationship with all the key terms that define the entrepreneurship starting with the definition of the term in the acceptance of important scholars in the field, such as Coleman and Putnam, understanding the entrepreneurial process and ending with concrete results of two studies conducted in business private environment and academic field. Even if the two models analyzed are targeting a different audience and materialize into different situational approaches, the outcome leads eventually to a similar conclusion, positioning social capital as an accelerator of innovation and new opportunities, but also as a connector among existent and potential entrepreneurs.

## **The Influence of Social Capital and its Components in the Entrepreneurial Activity**

In order to understand the correlation between the social capital and entrepreneurship, one key stage is to frame the conditions that the later one addresses. In the modern approach (Shane 2004) entrepreneurship is related to recognizing windows of opportunities within or outside the firm, market or industry through innovation and growth, by leveraging these opportunities to a large scale in order to satisfy people's unmet needs, by attracting the right human and financial resources and by partnering with strategic stakeholders, assuming in the same time a certain level of risks and uncertainty. In order to be able to identify the areas that an entrepreneur can penetrate, one of the strategies he or she needs to implement is to always remain externally connected with stakeholders, key influencers, actual or desired partners. Considering Putnam's concepts of bonding and bridging social capital (Putnam, 2000), an entrepreneur can actually seize business opportunities by direct or indirect networking with partners or clients activating in the same business environment or by interacting with individuals or entities belonging to a different field or market. However in order to be successful, one needs to be inclusive and remain linked to both communities, by encouraging the interpersonal connections, in order to create wealth for the company and for the society. In one of his lectures, Putnam who previously acknowledged that "Social networks have value...social contacts affect the productivity of individuals and groups" (Putnam, 2000), reiterates this idea in one of the lectures held at Manchester Metropolitan University. His speech contains one real business example where Business School in Chicago computed the dollar value of the address book for the average America, giving this way to the social network a financial dimension. (Putnam, 2007). In the context of a new start up, the networks and the social relations, as well as the existence of string ties with actors playing in the business can ensure the attraction of funds from venture capitalists. (Cable and Shane, 1997).

Another component of social capital, besides the social networking that brings added value in the entrepreneurial activity is related to the information channels and its broadcast in a free cost environment. A similar dimension is recognized by Coleman who refers in his study to those actors interested to acquire some degree of knowledge in a certain domain, without being willing to pay for the information, reason for which they make use of the social relations, so that social capital becomes a public good. (Coleman, 1994) Similarly, the opportunities seekers can collect information from different communities they belong, from associational activities they are involved in, that eventually might materialize into serious business propositions. The process of decision making becomes dependent on the information collected from suppliers, distributors, clients and even competitors (Bruderl and Preisendorfer, 1998; Bosma et al., 2004). Therefore in order to take advantage of this information, the providing sources of information need to be reliable; this way the presence of trust, as component of social capital becomes mandatory. Considering the classification of trust provided by Dakhli and de Clercq (2004), the trust can be of two types: generalized and institutionalized. This differentiation becomes extremely important when understanding that an entrepreneurial activity is not a standalone activity, but this is performed in a highly complex environment, ruled by governmental laws and business policies. In order to be successful, an entrepreneurial organization must embrace both the general trust, invested and

expected at individual level and institutional trust, invested and expected from the relationship with the other organizations and institutions.

Based on the above considerations, social capital remains a very attractive intangible asset (Adler & Kwon, 2002) as it reduces the transaction costs between the individuals and entities, the negotiation costs, the information and knowledge cost and the ones of the decision (Maskell, 2001; Landry et al., 2002).

By analyzing the current literature, we can identify a variety of different studies conducted in the industry that acknowledge the significant economical value that social capital has. This is highly contributing to the entrepreneurial process through its components, such as social contacts, social networks, trust, associational activities or civic norms. These studies use various approaches of highlighting the correlation between social capital and entrepreneurial activity, by analyzing the likelihood to launch new ventures based on the interactions with key partners and exchange of information, the sustainability and success of a start up or push/pull factors that determine an entrepreneur to enter the new ventures environment. For this article I chose two of these focused studies to reflect the strong relationship between social capital exploit and the success entrepreneurial outcome. However there are more similar researches conducted in different regions, business sectors, involving diverse actors, while centralizing them will make the object of future article. One example of these case studies is the Emerging Entrepreneurship Workshop conducted by Stanford University (Audretsch, Aldridge and Sanders, 2011), focused on building connections between investors, academicians and potential employees that would be leveraged at a later stage as innovation accelerators in creating a start up in the medical area. The study is based on a parallel between groups that had previous connections before their interaction at the workshop and the ones that met for the first time in the meeting facilitated by the University. The study is conducted on a period of three years after organizing the event, analyzing the baseline level of social capital and how this acts as an enabler for the interaction among potential partners that share and exchange information for creating new ventures. Based on the survey conducted at Stanford, three years after the conference, the outcome reveals an increase with thirty percent of the number of startups created by attendees of the conference. The results of the survey rely on a response rate of 46% of the individuals with prior connections and relations in the participating audience, The figures published by the University demonstrates the hypothesis according to which the social capital empowers the actors in materializing innovative ideas and accept challenges and uncertainty, after sharing opinions and asking for guidance from trusted counselors and advisors. Another important achievement of this study is the series of qualitative feedbacks collected from the participants to the conference that acknowledge the importance of interacting with actors from the same business area: "I've built more relationships as a results of the Emerging Entrepreneurship Conference than through other means by at least an order of magnitude" (Audretsch, Aldridge and Sanders, 2011:161). Such statements provide important reason to believe for the future sessions of this conference, encouraging current or potential entrepreneurs to join and benefit of their ratio of social capital. Professor Nalan Yetin conducted a research on 304 female entrepreneurs in Mersin, Turkey with the objective of understanding the degree of influence of social capital and sociocultural characteristics on the business success of the respondents (Yetin 2008). She references the push and pull factors in order to clearly differentiate between the two contexts that determine the females to start up their own ventures.

In her study, the professor considers also the demographic factors such as the age and social capital dimensions, such as the capability to build strong, weak or mixed ties in order to succeed. Professor Yetin introduces as input variables the status of migrant versus non migrant and the social class the females belong to, in order to understand the interdependency between the high usage level of the interpersonal relations and the entrepreneurial personality characteristics. Being a citizen of Mersin, or on the contrary, being relocated from outside the city was closely connected to the factors that determined their choice of becoming an entrepreneur and also contributed significantly to their ability of using social networks to their best advantage. Based on the outcome revealed by the research, the migrant women, belonging to the lower social class start up small businesses, in order to provide material support to their families, overcome difficult business conditions or gender discrimination (push factors). The same research reveal that non-migrant female, members of the middle and upper class use these opportunities to demonstrate their financial independence and autonomy in front of the other family members, to reach a superior level condition or establish an equilibrium between the personal and professional life (pull factors). Closely connected to the females' social status and consequently to the level of roadblocks to be prevailed, is also the usage of the social ties, of the strong ones or of the weak ones. The migrant women tend to maintain strong relationship with their family, relatives and the communities they belong to in order to entrust in their full support in achieving the desired goals, registering a high level of social capital. On the contrary, the non migrant female entrepreneurs prove a lower level of social capital, as they are not focused anymore on bonding or bridging new relations, but they are concentrated more on risk taking and reach a certain level of self-esteem.

These are two of the diverse spectrum of studies that were initiated on analyzing the relationship between social capital under different forms and components and entrepreneurial activity, with particular emphasis on the new ventures and start ups. However the entrepreneurial characteristics are not exclusively related the small-medium start ups, but also to large corporations. Considering Shane's perspective on the entrepreneurship (2004), the main characteristics of this activity which include recognizing innovation solution for unsolved problems or unsatisfied needs within or outside the firm, markets or industry, leveraging these opportunities to a large scale and assuming unknown risks and uncertainties, are applicable also in large corporations and multinational companies. Creating new business model, launching subsidiaries in emerging markets, simplify or eliminate existing processes by innovation and benchmarking are just few of the approaches that a corporation can undertake in order to classify itself as an entrepreneurial organization.

The following section of the article will approach how social capital is perceived in the large corporations, its structure and dimensions in strong connection with the entrepreneurial activity of these organizations.

### **High Level Introspection of Social Capital In Corporation**

Nowadays, the corporations acknowledge the difference between knowledge capital, human capital and social capital and the importance of each of these three dimensions has on the overall performance of the employees, materialized in the level of innovation and entrepreneurial spirit of each individual. If the human capital and knowledge capital have been accepted by now as main success drivers for the entrepreneurship and included in the speciality literature as prompts for innovation

and economic growth (Lucas, 1988; Romer, 1986; 1990), the previous case studies presented in this article are designed to bring the social capital in the spotlight, as main competitive advantage enabler and innovation generator for new ventures and start ups, wherever the level of human capital and knowledge capital are comparable.

Similarly as in the new start ups, the social capital created, maintained, pursued and implemented in a corporation can be defined as an intangible form of capital, resulted from the cumulus of the networks that are created within or outside the company, based on a relationship of trust and affiliation to a certain set of shared norms, values and principles which are generated collectively, but can be used individually in order to innovate, grow, add value to the overall entrepreneurial activity of a corporation. Social capital is rooted in the strong and weak ties, internal and external connections created at individual level by each employee in the organization, at corporation level through the interactions of the headquarters with different divisions and at company level, through the interaction with stakeholders and shareholders. Given the global dimension of a corporation, one special characteristic is the possibility to create social capital outside the boundaries of the company's headquarters, in each market and location where a subsidiary is present or the services/ products of the company are available.

Related to the above definition and considering some of the highlights existent in the literature (Hazelton& Kennan, 2000; Nahapiet& Ghoshal, 1998; Tsai& Ghoshal,1998), there are three dimensions social capital can take within an organization: structural, relational and cognitive. The structural dimension defines the actors' capability to build powerful or vulnerable bridges with the other individuals within a common system of reference, but it also refers to the individual self equity. Hazelton and Kennan (2000) add four key enablers to the structural dimension: availability of the network channels, the timing and the fast reaction implementation of the information that is being shared, the frame of reference indicating the availability and accessibility of resources and leveraging the information and resources for additional objectives and goals than the ones initially proposed. Considering the corporation's presence in different markets, countries and even continents, the variety of social capital –which is dependent on the number of employees and teams within the organization is greater than in the new start ups; similarly the number of potential networks and communities that can be created is significantly higher. The size of the social capital is also determined by the external ties that are created outside a corporation; therefore when considering the number of strategic stakeholders that a corporation can partner with, including the suppliers, distributors, clients, consumers and even competitors, the number of social relations and networks given birth from these interactions is significantly greater. Also from the timing perspective, the creation of these social relations is encouraged to take place as soon as an individual is joining the company, as soon as a new team is being created or right after a partnership is being signed, as this is frequently included in the corporation's set of principles, values and policies. Moreover, the resources that enable the creation of social capital are available on the spot, encouraging the actors to embrace them immediately, but also pass them over when transferring a certain activity or area of knowledge to new members in the company or to new partners in the external relations.

The relational dimension focuses on the type of connections that are established within the individuals and the level of trust that is created, as well as the entire set of

other beliefs that serve as a connector between the members of the community they belong. The set of beliefs refer to the identification-the perception of the actors related to how connected they feel with the others and the degree of social system closure and also to the implementation of civic norms which trigger sanction for those members, part of the system of social capital which don't respect the common values anymore (Hazelton and Kennan 2000). The relational dimension is very well reflected by Yoshio Maruta, Kao's chairman: "if anything goes wrong in one department, those in the other parts of the organization should... help without being asked." (Ghoshal& Barlett, 1995), highlighting this way the high level of trust that is expected and unquestioned by the leader of an organization. Actually trust is the milestone based on which the success of any company is built: it's the trust invested in each employee that assumes the ownership of their work, the trust in the leadership of the company to manage successfully the entire organization, the trust in the stakeholders which will play as advocate for the company's value, the trust of the investors that will provide ongoing support for the company's activity. The affiliation to the same set of norms and values is also important both for the actors within the company and the partners from outside, as this is also contributing to the creation of social capital. The cognitive or the content dimension defines the shared level of information and knowledge leveraged within one or several groups. According to the same Hazelton and Kennan (2000), from the content dimension, there are four sources that create social capital: information exchange, problem identification, behaviour regulation and conflict management. Given the large number of networks and communities built and the volume of information flow within a corporation, the cognitive dimension can reach high limits.

## **Conclusion**

Social capital is a valuable key enabler for entrepreneurship, regardless it's created as a base for the newly start-ups or within the premises of a corporation. The objective of the paper was to introduce the theoretical concept into the entrepreneurial framework and compare the outcomes of previous researches in the field, in order to highlight its positive influence on innovation, transaction costs between the individuals and entities, the negotiation costs, the information and knowledge cost and the ones of making decisions (Maskell, 2001; Landry et al., 2002). Additionally, starting from the idea that the corporations are also entrepreneurial organizations and the concept of social capital is also present at this level, I tried to identify the structure and dimensions, based on the theoretical concepts available in the literature. The review of different studies and the interactions I had with the entrepreneurial environment determine me to believe that nowadays there is particular focus of the companies on the social dimension of their activities, especially in the large corporations, when it comes to the level of social capital created within and outside of their premises. Regardless if we are considering social networks, trust, shared norms, shared values or principles, all these components are being perceived and generally recognized as significant differentiators for the organization's success and long term sustainability and this is also highlighted by the two case studies presented in the paper. In the context of entrepreneurship, whenever considering newly starts ups or mature organizations that are still focusing on identifying the right window of opportunity, I believe that innovation is the key. How to boost the sources of innovation, such that the breakthrough on the market is imminent represents a challenge that almost every

leader is facing. I strongly consider that social capital is one factor that can be leveraged in order to address this strategy and build a culture of innovation, such that each individual in the organization proposes an idea for simplification or digitization, considering in the same time the internal rules and policies to be respected. This behaviour can only be encouraged, by inspiring trust, confidence in the leadership, organization and the company's values and principles, but also by the care for the community where the company is activating. Another key component that is positively influencing the culture of innovation is the free flow of information and this can only be achieved through networking, bridging and bonding interactions. The networking can be enabled at different levels: interactions among the employees, interactions with different peer companies, part of the same group, interactions with the community, interactions with suppliers, customers, but in the end the outcome can only be a positive one- having access to free information that eventually might translate into innovative ideas, fast decision making, on spot implementation and increase in the customers' satisfaction.

However how much social capital the multinational companies actually create, compared to what exactly they claim to and how this level of social capital influences the overall performance of the organization represent the object of future researches and articles.

**Abstract:** *Starting with J. K. Galbraith who conceptualized what “good society” means and how it can be achieved, a long series of both theoretical and practical concerns has emerged. One way of implementing it is companies’ social responsibility. Companies are parts of the society, involved in social, cultural and educational field, contributing to economic and social development by creating jobs, producing goods, providing incomes and resources for public communities, innovations and general progress. Moreover, the companies’ social responsible actions cannot exclude the concern for major problems of the society, e.g. unemployment and social exclusion, equal chances or environmental issues. The social responsible companies involve themselves more and more in sponsorship and humanitarian mecenatum. At the same time, on the theoretical side, last decades testified of an effervescence of the researches on practices related to the concept of corporate social responsibility. Whilst so far corporate social responsibility is mainly promoted by a number of large companies, it is relevant in all types of companies and in all sectors of activity, from SMEs to multinational companies. A number of companies with good social and environmental records indicate that these activities can induce better performance and more profit. The paper investigates various issues concerning Romanian companies’ CSR projects, attempting to reveal to what extent these actions really contribute to a “good society” or they are just business strategies to attract customers and make more profit. In its first part we introduce the subjects and briefly review the literature and main concepts, while in the second part we present main facts and figures related to CSR in Romania, along with the main types of companies’ involvement in social and humanitarian area. We analyse the differences between behaviour of large companies versus small and medium sized companies, and also the most adequate forms of intervention (financially and legally) to ensure maximum efficacy and visibility of CSR actions. Finally we conclude on the importance of CSR within society but also on the risk that it could be converted in a business strategy or marketing tool, without any social impact.*

**Keywords:** *corporate social responsibility, good society, Romanian companies, business strategy*

## **1. Introduction. Corporate social responsibility for a “good society”**

John Kenneth Galbraith defined the essence of the good society as follows: "It is that every member, regardless of gender, race or ethnic origin, should have access to a rewarding life. Allowance there must be for undoubted differences in aspiration and qualification. Individuals differ in physical and mental facility, commitment and purpose, and from these differences come differences in achievement and in economic reward. [...] No one, from accident of birth or economic circumstance, may be denied these things; if they are not available from parent or family, society must provide effective forms of care and guidance" (Galbraith, 1996). Undoubtedly, the desire of a better society exalted minds of tens of philosophers, sociologists or economists, but never like in the last hundred years the world was never more far away, and, at the same time, closer to this ideal. What is, however, a better society? The utilitarians define better society as one that can best meet the needs of as many members of society; others see it as the organization that provides and ensures an equality of chances among citizens, while left-wing militants imagine better society as one that ensures a fair distribution of results among citizens. Amartya Sen suggests an alternative approach, recalling that certain modes of society are essential for a better human life: meeting the physical needs and physical security, taking decisions on an informed basis, the existence and exercise of civil and political rights (Sen, 1999).

Could be the modern enterprise an agent of a better society? It is possible that its fundamental purpose: to generate profit, to work in line with social concerns?

The company is a part of whole society, acting as an active actor in social, cultural and educational field. The company contributes to economical- social development by creating jobs, products/goods, values, incomes, resources for public communities, inventions and widespread of technical progress. In the same time, the company's social responsible action cannot exclude the concern for major problems of the society as unemployment and social exclusion, equal chances or environmental issues. The civic company is concerned by issues related to ethics, to conduct rules promoted by the community of the entrepreneurs, in order to achieve certain goals.

## **2. The concept of corporate social responsibility and its meanings**

As many other modern concepts and concerns in the economic theory and practice, also in the case of corporate social responsibility (CSR) the origin has to be searched long time ago. Adam Smith, before writing his master piece *The Wealth of Nations* (1776), wrote *The Theory of Moral Sentiments* (1759), providing the ethical, philosophical and methodological basis for his later works. Later, Adam Smith argued how, paradoxically, the individual selfish behaviour drives to collective interest achievement, by the natural intervention of the invisible hand of the market, of course in a perfect competition environment: "... In spite of their natural selfishness and rapacity, though they mean only their own convenience, though the sole end which they propose .... They are led by an invisible hand to make nearly the same distribution of the necessaries of life..." (Smith, 1904).

However, the silence covered all moral, ethical and social responsibility issues of the companies for almost two centuries. In the early of last century, Oliver Sheldon (1923) encouraged management to promote ethical standards and justice in society through an efficient resource usage and only in 1953, Howard Bower, nicknamed 'the father' of the social responsibility of the company, defined corporate social

responsibility as: “the obligations of businessmen to pursue those policies, to make those decisions or to follow those directions that are agreed in term of values and goals by our society” (Bowen, 1953).

In the last decades, we assist at an effervescence of the concept and practices related to the concept of CSR, all over the world. Keith Davis and Robert Blomstrom (1975) define the concept thus: “Social responsibility is the obligation of decision makers to act in order to protect and enhance the well-being of the society as a whole, besides the necessity to protect their own interests” and Joseph McGuire (1963, p. 74) stated: “the idea of corporate social responsibility assumes that a corporations do not have only economic and legal obligations, but also responsibilities toward the community where it activates”.

Overall, we can say that most definitions of CSR describe it as an integration of social, public, human and environmental concerns in their business activity and in their interaction with the stakeholders on a voluntary basis. Being socially responsible means not only fulfilling legal expectations, but also going beyond compliance and investing in human capital, the environment etc., investment which is assumed as a driven factor of the company’s competitiveness. CSR is a concept referring to the contribution that companies should have to the modern society development. The wide variety of theories and approaches to CSR can lead to confusion, especially when many authors try to broader the content to these theories, diluting their meanings. In a systematization undertaking, Secchi (2007, pp. 347-373) recognizes three categories of these: the utilitarian theory - addressing social costs issues and functionalism, 2) The managerial theory - Corporate Social Performance, Social accountability, auditing and reporting, social responsibility for multinationals, and 3) the relational theory dealing with Business and Society Stakeholder Approach, global Corporate Citizenship and Social Contract theory. From another perspective, Garriga and Mele find that CSR’s theories cover four distinct areas: instrumental, political, integrative and, finally, ethical theories. For the latter they associate those actions that, in their moral and correctness, lead to implementing the ideal of a better society (Garriga & Mele, 2004) and (Ismail, 2009, pp. 308-318). Whilst so far CSR is mainly promoted by a number of large or multinational companies, it is relevant in all types of companies and in all sectors of activity, from SMEs to multinational companies (MNCs). For many companies involved in these activities, the economic impact of corporate social responsibility can be broken down into direct and indirect effects. Positive direct results may derive from a better working environment, which leads to a better motivated and productive employees and a rational use of natural resources. Indirect effects result from the growing attention of consumers and investors, which will increase their opportunities on the markets. Inversely, we notice negative impact on a company’s reputation due to criticism of business practices, affecting the core assets of a company, such as its brands and image.

CSR has two different dimensions: the internal dimension and the external one. About the internal one, socially responsible practices primarily involve employees and relate to issues such as investing in human capital, health and safety, while environmentally responsible practices relate mainly to the management of natural resources used in the production, reconciling social development with improved competitiveness. The external dimension involves also the business partners and suppliers, customers, public authorities and NGOs representing local communities, as well as the environment. Moreover, the globalization has encouraged the

development of "global governance": the development of voluntary CSR practices can be seen as contributing to this (Commission of the European Communities, 2001).

At this point, we cannot ignore that CSR could be, in the absence of a real commitment solving social and ecologic problems, just as an empty box. Milton Friedman said that "The discussions of the "social responsibilities of business" are notable for their analytical looseness and lack of rigor. What does it mean to say that "business" has responsibilities? Only people can have responsibilities. A corporation is an artificial person and in this sense may have artificial responsibilities, but "business" as a whole cannot be said to have responsibilities, even in this vague sense" (Friedman, 1970). Thus, we could differentiate the critics of CSR into two main trends: first, the most active, coming from the defenders of free market principles, taking arguments of Milton Friedman - the only social responsibility of business is to increase profits, accusing world business leaders have abandoned the principle of efficiency in favour of so-called "political correctness". Recently, some critics come from the leftist area of (American) democracy. Thus, Robert Reich denounces CSR as a dangerous diversion that undermines democracy, considering that companies "can not be socially responsible, or at least to a significant extent," and CSR activists should insist to make governments primarily responsible in setting standards and norms, in order to avoid companies to act against the interest of society (Reich, 2008). Moreover, crediting firms with socially responsible actions when they actually seek economic effects thereof, is dangerous, because extends this category of CSR over all firms actions in profit seeking and competition. For Timothy M. Devinney (2009) "the notion of a socially responsible corporation is potentially an oxymoron because of the naturally conflicted nature of the corporation".

Without getting into a controversial debate on CSR, some issues remain: whether firms that are involved in these actions are/become more profitable, if CSR's actions should not be understood as a form of "smart management", and, the last, but not the least, we have to accept that is unlikely companies to do things against their self-interest. To fundamental reject these actions is as we show to the companies they don't need act responsibly. It might cause them to under-invest in these opportunities, and to focus excessively on short-term profit (The Economist, 2007).

### **3. Corporate social responsibility in Romania**

In Romania, the concept of social responsibility has appeared in Romania after 1990 when many NGOs - associations and foundations were set up with the help of international public or private institutions, especially with a humanitarian role, for helping some disadvantaged categories: children, elder people etc. Following the social initiatives, the concept of CSR was introduced by big multinational companies entered in Romania and pursuing and promoting global projects and programmes, e.g. Coca-Cola, Pepsi-Cola, Philip Morris etc., the majority of them joining the American-Romanian Chamber of Commerce. After 2000, many other business companies, both large and SMEs, started to involve in actions of social responsibility, especially involving environmental and social issues.

According to a 2007 report regarding CSR and competitiveness regarding the situation of CSR in Romania, the corporate responsibility, far from being ignored or viewed with apathy, is simply expected in some sectors of Romanian business (CCIR, et al., 2007). The standard CSR terminology and language is not universally

understood, but fair pricing, health and safety, good working conditions, community involvement and environmental protection are all high on the list of public/consumer concerns. At the middle of 2000, Romania, as many Central and Eastern countries come to terms with rapid economic growth and that was an opportunity for businesses to stand up to the challenge and help fill the social vacuum left by the demise of Communism. By doing this, businesses can help to guarantee the stability of Romanian society. Many businesses operating in Romania were taking their responsibilities seriously, but many more preferred the easy route: using PR to artificially alter public perception.

In Romania, the first significant activities stimulating companies to be part in social activities was TOP Corporate Philanthropist, by granting diplomas, awards, public recognition to companies involved in social projects. Thus, in 2006, were mentioned names as BRD - Groupe Société Générale, Ductil SA, IMPACT SA, DotCommerce Romania (Forumul Donatorilor din Romania/Romanian Donors Forum, 2012). In the following year (2007), the corporate donations increased, as Romania was ranked second in the CEE region, after the Czech Republic. Although the amounts were relatively modest, the increase was significant: from nearly 3 billion in 2006 to about 8 billion in 2007 (Forumul Donatorilor din Romania/Romanian Donors Forum, 2012). The trend has continued, in 2008, top 10 among donors in Romania have invested over 12 million euros in social responsibility projects and top 10 corporate foundations have funded civil society with over 6.4 million Euro. Petrom SA was considered the most generous large companies and Vodafone Romania Foundation was named winner in corporate foundations sections (Euractiv, 2009). In time, the CSR budgets have constantly increased in the last years, as it can be seen in Table 1.

According to a research conducted by CSR Media, Romanian companies have invested in CSR projects about 16 million in 2011, and over 12 million in 2012 (CSRmedia, 2013). From this, approximately 16 million allocated to Social Responsibility projects in 2011, almost 11.6 million euros were invested by the Top 10 Corporate companies in Romania. The amount represents about 1% of their declared net profit. Most CSR investments in 2011 were made by companies operating in the oil, telecommunications and banking sectors; the largest budget of CSR, around 4.2 million in 2011, come, as expected, from the Petrom – the largest oil and gas producer in South Eastern Europe. According to the representatives of this company, between 2007 and 2012, Petrom has invested over 30 million euros in social responsibility projects, the most famous being "Andrei's Country" (Țara lui Andrei) (Craciun, 2013), "... a great community oriented to solutions that generate long-term value. We encourage both individual initiatives and those from organizations that create economic value for the community, but addressing social problems. We strongly believe encouraging entrepreneurship integrated with a community approach, we are able to make Romania a better country ... " (Forbes Romania, Craciun M., 2012).

**Table 1: CSR budgets in Romanian selected companies**

Company	CSR budget (in thousand EUR)						
	2004	2005	2006	2007	2008	2009	2010
A&D Pharma	300	500	550	670	350	400	470
Avon Romania	n.a.	n.a.	n.a.	242	338	254	n.a.

Tuborg Romania (URBB)	n.a.	300	n.a.	70	760	730	n.a.
Unicredit Tiriac	145	125	500	500	1000	600	650

Source: <http://www.responsabilitatesociala.ro/companii.html>

In aggregate terms, most of the amounts invested in the last 6-7 years were sponsorship, and only a small part in donations. The explanation is that Romanian legal framework, do not stimulating the donations: the procedure is complicated involving a donation act through notary offices and around 1%-2% taxes and notary fees. On the other hand, the sponsorship can be immediately granted, and their amount can reach up to 20% from the income tax, but not exceeding 0,3% from annual cumulated turnover. In the 90s, Romanian companies made donations in small amounts, especially for social causes, based on emotional impulse not on a policy basis, such as: the desire to help other people (39%), humanitarian reasons (17%), help children (10%), and help older people (8%). However, after 2000, things changed. There are now practiced all relevant form of companies' involvement in the community problems solving (ARC (1), 2006):

### 3.1. Donations and sponsorship

A survey conducted in 2003 by the Association for Community Relationship indicated that 29% of Romanian companies made cash gifts, while 24% made in-kind donations. Data shows that the number of companies located in small towns (less than 30,000 citizens) making donations is double compared with the number of businesses in big cities (50% vs 26%), but, as expected, the average donation and the total amount given increases proportionally with the resident location size. Concerning the distribution of funds according to the type of recipient organization, it reveals that the largest group of beneficiaries is NGOs with 18.4%, followed by schools and kindergartens (17.1%) and the Church with 16.5%. Related to the distribution of funds by fields, religion cumulate 13% from companies allocations,

followed by education and research with 9.8%, but only 1-2% from donors amounts reach to environmental protection, human rights and democracy causes. The data show that the average donation of companies in Romania is around 0.4% of their annual turnover, comparing with 1.2% of annual pre-tax income for an U.S company. As a general assertion, most business donors give rather small amounts (almost half donate less than US\$ 400 per year). However, these data must be seen in the context of the generally poor status of the Romanian economy. Only a minority of Romanian companies (12%) have significant budgets for donations (more than US \$3,500 per year). In terms of frequency of giving, a quarter of companies make donations more than five times per year, and another quarter donate just once a year (ARC (2), 2003) and (ARC (3), 2003).

Romania is still behind other countries in the region. In 2006, the overall value of the donations from Central and Eastern Europe companies (Russia included) was 127.7 million euros, according to "Central and Eastern European Network for Responsible Giving". If on local side, in 2006, the first 10 companies from the Romania Donors Forum provided almost EUR 3 million, the top 10 companies in the Czech Republic provided EUR 25.6 million, and in Slovakia EUR 3.5 million. In Hungary, the amounts offered by the companies for the non-profit organizations reached EUR 6.3 million (Anton, 2008). However, the attitude of Romanian companies to CSR tends to improve. Comparing with individual donor patterns, here there is a strong consensus between analysts that progress has been highly visible in the last years regarding a highly visible progress. Thus, in the last 5-6 years, the amounts given by larger, national scope corporations range between 3,000 EUR – 500,000 EUR, depending on size of project or its priority and significance for the company, on the corporate philanthropy market. Still, most of these situate somewhere in the 5,000 EUR – 50,000 EUR range (Porumb & Sofica, 2008).

The research has shown that the dynamics in the corporate giving is linked to the pioneering example of multinational companies who have developed frameworks for social corporate in their headquarters or already have experience in this area. While national companies prefer projects with national coverage, there are also local examples or CSR projects undertaken by local SMEs, or by decentralized structures and components of large corporate initiatives. This shows clearly that there are sufficient opportunities and needs where CSR programs can be developed in the future. Although most (primary) data provide information on large firms initiatives and behaviour, of their involvement in large projects, particularly visible through adequate advertising support (sometimes extensions of international campaigns), there is also a relevant dimension of CSR in the local firms. Interestingly, the data shows that small businesses tend to follow individual donors pattern, and less the corporate ones.

### **3.2. Salary donations**

This model is very common in the US and UK, its success being ensured by the incentives made by legal framework. The mechanism consists in monthly donations made by employees from their after-tax salary; usually, the company doubles the amounts and redirect the money to a non-profit organization. For Romania, it has to be mentioned some projects of great multinational companies, such as Coca Cola HBC Romania, Vodafone, United Way, Unicredit Tiriatic Bank or Raiffeissen Bank. Every year since 2004, Coca Cola HBC Romania involved its employees in a salary donations program, for supporting a school choir, an institution for old people and a

school for disabled children. Vodafone started to practice this mechanism in 1998, the beneficiaries being individuals in risk situations, orphan children, ill persons, and institutionalized old people. Also, Matching Gift Program initiated by UniCredit Foundation in 2003 (continued annually until 2011), aims to provide support to children and disadvantaged people (Responsabilitate socială, 2012).

### **3.3. Corporate volunteering**

Volunteerism is a key component of many companies' philanthropic and community affairs programs. Corporate volunteerism can be a triple win: helping people in the community while giving employees a chance to shine and benefiting the company in numerous ways. The company encourages its employees to put their time, ability or expertise in the service of an organisation or of the community itself.

At European level, Business in the Community (BITC) has launched a competition in 2011 in 22 European countries (including Romania) and awarded corporate volunteer programs. Initiative called "Employee Volunteering Awards" was co-funded by the European Commission. It took place in the context in which 2011 was declared "European Year of Volunteering" (CSR Europe, 2012). Some examples for Romania are: Lafarge Romania, that made a long term partnership with Habitat for Humanity Romania, supporting the construction of houses for poor people; GlaxoSmithKline in a partnership with the Hospice House of Hope, providing personal care for ill persons in terminal phase (Voluntariat.ro, 2012).

### **3.4. Corporate foundations**

The corporate foundation is a non-profit independent entity, financially supported by a company. The amount of the fund raising is quite impressive in some cases and it includes grants, scholarships, employee matching gifts, and other amounts; for example, in the US, the largest grant making foundation is Bill and Melinda Gates, with an amount exceeding US\$ 2bn., followed by many other corporate foundations as Lilly Cares Foundations, The Ford Foundation, The William and Flora Hewlett Foundation (Foundation Center, 2013). In Romania, the most important foundations belong to multinational companies, such as Partners for Life, settled by GlaxoSmithKline, Ronald McDonald, Sirois (Vodafone) but there is also a national example, the Sensiblu Foundation, settled by A&D Pharma. Now there are registered more than 100 corporate foundations, but only 15 are consistently involved in philanthropic acts. Some of them co-operate with non-profit organizations for project achievement (MOL Romania, Vodafone, Coca-Cola, Anchor Group) and some create their own programs (RTC Foundation).

### **3.5. Cause Related Marketing**

Cause Related Marketing is an undertaking assumed by the company to direct for a well-defined cause a part of the profit earned from a specific product or service for a limited time period. This practice is more efficient for companies, since for 70% of the consumers, the social involvement of the company from which they buy products is important in the choice process and 20% of them are even willing to pay more for the products provided by a socially involved company (CSR Europe, 2012). Some examples for Romania include: the project *A computer, an extra-chance for the future* (Procter&Gamble 1999), *Together for the Children* (Kraft Jacobs 2002), *Together for the Future* (Vodafone 2005), *Chance to life, chance to new memories* (Procter and Gamble Romania, 2008), *UNICEF Cards - 1%* (Unicredit Tirioc Bank,

2010), *Soft Toys for Education Campaign* (IKEA Romania, 2010, 2011, 2012), One Pack = One Vaccine (Pampers Romania 2010) (Responsabilitate socială, 2012).

#### 4. Conclusion

The main conclusion is that in Romania there are still important differences between multinational companies operating in the country and national companies, and also differences between big and small/medium size companies. Companies still use rarely the charity action, moreover, companies did not completely understand the importance of these actions for marketing, PR and enhancing image, maybe, perhaps NGOs are not perceived as potential vehicles to enhance the company's image, or many companies do not have the ability to integrate corporate philanthropy in PR activities or marketing strategies. However, in the last decade, the international trend to adopt a CSR strategy is followed more and more by local companies, which are in the process of building a medium term strategy for involving in community. CSR is undoubtedly a real gain of social and humanitarian perspective in society. The realities of the Romanian economy and society of the last years have captured both the wave of models, the enthusiasm and involvement of corporate sector in social problems, both the impact of economic crisis on the continuity and real sense of social projects, regardless the size and power of their supporters. In order to maintain the social value of CSR and to give a real sense to business ethics, the CSR managers should try to temper their desperately seeking of convincing evidence that "doing good is good for business" i.e. to avoid passing in the CSR payment bill the costs of every current and strategic business decisions. Invoking the monotonous and sometimes aggressive business motto rather creates doubts that it would not be self-evident that the emerging and functioning of the companies, the business in general are not based on the needs of society but rather on occult and unethical reasons.

# MODERN INDICATORS DERIVED FROM VALUE CREATION AND DISCOUNTED CASH FLOW METHODS

**Cican Simona, Lala – Popa Ioan, Aniș Cecilia-Nicoleta**

*Management Department, West University, Faculty of Economics and Business Administration, Timișoara, România*

*simona.cican@yahoo.com*

*ioan.lala@feaa.uvt.ro*

*anis\_cecilia@yahoo.com*

**Abstract:** *The manner in which resources are allocated, the generation of cash through present resources and the allocation of new liquidities derive from a company's cost-benefit analysis, which is part of management control. The modern financial theory changes the company management objective of maximizing profit with the objective of maximizing its value. The traditional return measures are considered to be insufficient to express the economic reality. Traditional cost-benefit indicators exclude opportunity costs, effects of inflation and risks. The financial experts claim firm value maximization as the main objective of a company's management. The emergence of modern return measures derived from firm value maximization reflects the changes in the economic environment, their emergence creating a dispute over the most appropriate approach regarding value creation. The fact that the data required for their calculation is taken directly from accounts makes them sensitive to accounting distortions. The emergence of modern cost-benefit indicators derived from value creation provides new perspectives on the return. Firm value can grow by generating a higher level of cash flow, by reducing financing costs and by extending the growth period. The value created can be measured by using both modern indicators derived from the theory of value creation and discounted cash flow methods. The value created can be calculated by using discounted cash flow models, which, moreover, are very complicated and take into account a lot of variables. The alternative to these methods is represented by modern cost-benefit indicators that have a more simple calculation methodology, and the forecast of calculation factors is narrower and easier to accomplish.*

*In this article, we will present the connection between discounted cash flow methods and the indicators derived from value creation, based on the business finance theory, which says that firm value will increase if projects with positive net present value are accepted, while it will be destroyed if projects with negative net present value are accepted.*

**Keywords:** *modern return measures; economic value added; discounted cash flow model; the net present value; the internal rate of return; cash flow return on investment.*

**JEL Classification:** *G32; M21.*

## **1. Introduction**

Since the 1990s, the traditional return measures are considered to be insufficient to express the economic reality. The financial experts claim firm value maximization as the main objective of a company's management. The emergence of modern return

measures derived from firm value maximization reflects the changes in the economic environment, their emergence creating a dispute over the most appropriate approach regarding value creation. The cost of financing sources is one of the primary factor in foundation financing policy, having the greatest impact on company results and hence on its value (Pirtea, Boțoc, and Nicolescu : 2010).

The value created can be measured by using both modern indicators derived from the theory of value creation and discounted cash flow methods. Modern performance indicators require less information than the traditional approach of discounted cash flow, and some believe that they are better at expressing value.

## **2. Modern Performance Indicators Derived from Discounted Cash Flow Methods**

The Discounted Cash Flow Method is a standard procedure of the modern financial theory that provides perspectives on how a company can create value. This model is widely used in investment finance, real estate development and corporate financial management, which is why in practice it enjoys great importance and is considered to be the basic method of estimating firm value. Since 1929, the discounted cash flow analysis gained popularity, it being used for estimating shares. The Discounted Cash Flow Method is expressed formally in modern economics by Irving Fisher in 1930 and John Burr Williams in 1938.

Firm value is the sum of all future discounted cash flows at the risk of bearing debt. Firm value can also be regarded as the sum of the value of all assets – where asset value is given by the discounted cash flow resulting from the operation of the asset (Damadoran, A., 2002). In other words, cash flow resulting from a company's businesses is discounted at a rate that equalizes their risk. The formula for calculating firm value by using the discounted cash flow method is:

$$VF = \sum_{i=1}^{n-1} \frac{CF_i}{(1+a)^i} + \frac{RV}{(1+a)^n}$$

where: VF = firm value;  $CF_i$  = cash flow in year  $i$ ;  $a$  = discount rate; RV = residual value at the end of the period;  $n$  = life cycle of investment expressed in years.

To evaluate a company, both cash flows generated by the business and the expected growth value are needed. Therefore, the following should be considered:

- Free Cash Flow - is the monetary expression of business operations result, representing in fact the cash that returns to investors: shareholders, debt holders, preferred shareholders etc. It can be derived from the operating cash flow from which the cash required for the business development and the development of production capacity. The variables will be estimated based on a strategic analysis of the company's development potential, which must take into account the internal and external potential of the company.
- Expected Growth - it can be obtained based on the reinvestment coefficient multiplied by the return on capital. The reinvestment coefficient is calculated as the ratio of the net operating result, which is invested in net capital expenditures and non-cash working capital.
- Discount Rate - it is established based on the Weighted Average Cost of Capital model. The Weighted Average Cost of Capital is the weighted average of all costs involved in investment, equity and loan capital respectively. It reflects the cash flow risk. A common problem in practice is the cost of equity. To determine

the cost of equity, we may use the dividend discount model and the capital asset pricing model. The first model is the traditional method used and is based on the discount of dividends with the shareholders' required return, and the second shows the investors' risk premium through the relationship between the expected return and the risk assumed.

- Asset life cycle – residual value - the life cycle of every project has a finite number of years, upon which the forecast is based, which is why it is very important, both in terms of cash flow estimation for a well-determined period, and terminal value estimation.

In the discounted cash flow analysis, all future cash flows are estimated and discounted to give present value, and their sum is represented by the net present value.

The most common techniques using discounted cash flow is the net present value and the internal rate of return. These include the discount technique, their limitation being that they do not take into account depreciation. These dynamic methods for allocating capital resources are often used in the USA and UK, both in the public and private sector.

*The Net Present Value* is a discounted cash flow technique that indicated cash inflows and outflows discounted at the present value. It can be used both to analyze a business and for future projects or divisions of a company.

It is said that there is no difference between what net present value and discounted cash flow represent. Using these two methods is different from what is aimed to calculate:

- discounted cash flow method is used to evaluate complex investments that may have different assumptions regarding cash flow, multiple equations, inflows and outflows
- net present value is used to analyze projects with a well-defined life cycle including cash inflows and outflows that are easy to estimate.

*The Internal Rate of Return* equalizes the cash inflows and outflows at the present value. This dynamic analysis method is generally used to allocate capital resources for a certain project.

The Internal rate of return calculated with the net present value determines the expected rate of return and the discount rate that should correspond to the risk level of the project. In both cases, an internal rate of return may determine the expected total rate of return, and the discount rate should correspond to the risk level of the project.

The discount used as single technique, with no attachment to other evaluation criteria, may lead to certain projects, desirable at first sight, but not profitable. Therefore, multiple discount criteria, as well as traditional estimation criteria should be used in assessing the efficiency of an investment.

Modern performance indicators are said to achieve the same thing as the dynamic methods of investment assessment, i.e. discounted cash flow methods. Discounted cash flow methods are very complex because of the multitude of variables to estimate, and a bonus management system can not be drawn on their basis, as it is very difficult and not recommended, because the accounting data might be manipulated by executives in their own interest. Modern performance indicators are easier to calculate, use and understand, as the estimates made for their calculation are fewer and do not depend on market movements. Next, I will present two most

famous modern indicators for measuring performance: Economic Value Added and the Cash Flow Return on Investment.

*Economic Value Added* is considered to be the most common indicator for measuring shareholder value. Economic value added is a measure that allows managers to see whether they gain a proper return (Harper Collins, 1991). If the return is lower than the expected one for similar investments, resulting in a negative indicator, the company faces share price decrease and capital flight. One way to calculate the economic value added is to multiply equity by the difference between return on equity and its cost:

$$EVA = (\text{Return on equity} - \text{cost of equity}) \times \text{Invested capital}$$

To increase firm value, each project accepted must have a positive net present value, i.e. the internal rate of return generated by the project will be higher than the cost of equity. In practice, we do not employ the internal rate of return for measuring performance, but the traditional rates of return to estimate the rate of return on equity, although it does not indicate the real return (Storrie and Sinclair, 1997).

*Cash Flow Return on Investment* is defined as the gross annual cash flow related to the capital invested on business units (Lewis and Günther, 1997). Cash Flow Return on Investment corresponds to the average internal rate of return for a short period of an investment, based on the cash inflows and outflows of investments and their recovery. The calculation formula for this indicator is as follows:

$$CFROI = \text{Cash flow} / \text{Market value of capital employed}$$

or solution in formula: 
$$I = \sum_{n=1}^i \frac{CF_i}{(1+CFROI)^n} + \frac{W^{n+1}}{(1+CFROI)^{n+1}}$$

where: W – expected residual value of non-depreciable assets; I – Gross investment in operating assets; CF – gross cash flow; n – life cycle of investment

### 3. Critical Review of Modern Performance Measurement Indicators

#### 3.1. Economic Value Added versus Discounted Cash Flow Method

The rule of net present value is one of the analysis fundamentals of investment decisions in corporate finance. Economic value added is a return to the net present value rule. (Damadoran, 2002). It is well known that in order to increase the value of economic value added, projects with positive net present value should be accepted, otherwise, the adoption of projects with negative net present value decreases the value of the indicator. The cost of capital and the inflation are common aspects considered in the calculation of economic value added and net present value, and the adjustments made do not give place to accounting distortions.

Discounted cash flow / net present value and economic value added, in theory, have the same mathematical result. (Stewart, 1990). Stewart also stated that the economic value added formula is a modification of the discounted cash flow formula through a mathematical construction in which all adjustments made in calculating economic value added to the discounted cash flow must result net zero. He also mentions regardless of the starting capital used in calculating economic value added, the results are always the same.

Present value of economic value added of a project over its life is the net present value of the project.

Otherwise, a connection between economic value added and discounted cash flow model can be made (Damadoran, 2002). The amount of capital invested in assets

held, the present value of economic value added and the present value of economic value added of future projects is, in fact, the firm value:

$$VF = \text{Invested capital assets held} + \sum_{i=1}^n \frac{\text{EVA}_i \text{ assets in place}}{(1+a)^i} + \sum_{i=1}^n \frac{\text{EVA}_i \text{ future projects}}{(1+a)^i}$$

where: VF – firm value; n – life cycle of investment expressed in years; EVA – economic value added; a – discount rate;

Delimitations between net present value / discounted cash flow and economic value added:

- this equivalence between net present value and economic value added is sensitive to the book value of capital when calculating the economic value added. An increase in the book value of capital, which attracts a higher cost of capital, has as result a lower economic value added. The change of the two variables, as well as the fact that the market value of capital is always the same, regardless of the initial book value, shows a lack of relevance in determining the value (Storrie, Sinclair, 1997).
- the level of residual value and depreciation tax benefits make economic value added and net present value give different results. This is possible when the present value of invested capital is lower than the residual value or the present value of benefits from depreciation.
- the equivalence of the two methods is real before making the adjustments required for the calculation of economic value added, after that, they will lead to different results.
- firm value (seen as the sum of invested capital and the present value of economic value added) may decrease, even though the economic value added grows on the background of the operational risk increase and cost of capital supplementation.
- economic value added is a well-known measure, used for both performance assessment and for employee compensation. Discounted cash flow methods are useful in strategic planning (capital resources allocation) and assessment. It provides a picture of the necessary cash flows for business requirements and facilitates the understanding of short- and long-term risk.

Thus, the discounted cash flow methods are not used to measure performance and an employee bonus system based on it would be extremely difficult and unsatisfying. In evaluation, under certain conditions, the equivalence of economic value added and discounted cash flow methods can be met, but it does not express performance. Conversely, it comes into question whether the economic value added can be used for the same purpose for which discounted cash flow method is. Economic value added can neither provide a picture of the necessary cash flows for business requirements, nor an understanding of short-term and long term risk. Economic value added indicates whether the initial capital produces positive or negative levels, a measure that can have high levels with low initial capital, while the discounted cash flow analysis can indicate that the proposed strategy may lead to value destruction. When analyzing a company, one must take into account both the economic value added and net present value, and the internal rate of return and return on investment. The shareholder wealth is first considered, followed by the expected return. The economic value added and the return on investment are used to measure performance, while the net present value and the internal rate of return are used to determine a project's return. Future decisions of the company are based on the

economic value added and net present value, which provide information on the firm value maximization. It must be well defined that no decision should be taken based solely on rates of return, because they provide related data. Maximizing internal rate of return and return on investment is a wrong objective if it aims to increase shareholder return.

### 3.2. Cash Flow Return on Investment versus Internal Rate of Return/ Discounted Cash Flow Method

*Cash Flow Return on Investment* is an indicator similar to the internal rate of return (Damadoran, 2002). Cash Flow Return on Investment can be seen as both an after-tax rate of return on existing assets, and a rate that adjusts net present value of the cash flow generated by existing assets equal to the cost of investment.

*Internal Rate of Return* is calculated based on net cash flows generated by the project based on the initial investment (also taking into consideration the terminal value). Internal rate of return is compared with the cost of capital. This can be calculated as a nominal or real rate, depending on the nominal or real cost of capital. Mathematically, we can say that the Cash Flow Return on Investment has the same determination. It calculates a real internal rate of return based on the project's gross investment (initial investment) with the assumption that gross cash flow surplus in monetary terms is maintained throughout the entire life cycle of the project.

To highlight the relationship between firm value and cash flow return on investment expressed by using discounted cash flow, a number of variables should be taken into account, such as: gross investment, tax, growth rate, cost of capital and reinvestment needs of the company. Firm value expressed by using cash flow return on investment is as follows (Damadoran, 2002):

$$FV = \frac{(CFROI \times \text{gross investment} - \text{depreciation}) \times (1 - \text{tax}) - (\text{capital expenditure} - \text{depreciation}) - \Delta WC}{\text{cost of capital} - \text{sustainable growth rate}}$$

where: FV – firm value;  $\Delta Wc$  – changes in working capital.

One can see that firm value is influenced by both cash flow return on investment of assets held and the way this rate handles the cost of capital.

Delimitations between cash flow return on investment and internal rate of return / discounted cash flow method:

- cash flow Return on Investment is built on the premise that real cash flow does not increase over time, and the internal rate of return can also be calculated based on net cash flows that fluctuate over time. It is easy to conclude that Cash flow Return on Investment cannot be used for projects in markets with high growth potential;
- cash flow Return on Investment can be used in both retrospective and prospective analysis, and the internal rate of return can be calculated only for future projects;
- when the assessment of return is based on Cash flow Return on Investment, managers can increase the rate of return by subtracting gross investment, resulting in a lower firm value. Thus, an increase in the Cash flow Return on Investment may result in a decrease in firm value if it is done at the expense of an increase in value or by increasing risk.

### 4. Conclusions

Based on these theoretical approaches it can be concluded that:

- the financial theory regarding firm value argues that firm value will increase if accepts projects with positive net present value are being accepted. Economic value added and Cash flow Return on Investment are similar methods to consider net present value.
- if the main objective of the firm is to maximize value both in its strategy and culture, then any method used to increase value can work.
- economic value added is regarded as the present value of the expected economic profit, so it is considered to be the new equivalent to the net present value.
- cash flow Return on Investment can be seen as the after tax rate of return of existing assets, as well as the rate that adjusts net present value of cash flows generated by existing assets equal to the cost of investment.
- net present value and internal rate of return are used in the evaluation and strategic analysis of the company; economic value added and Cash flow Return on Investment are useful in evaluating performance; they can not provide information on understanding of short-term and long-term risk.

Modern performance measurement indicators are easier to calculate, and data considered in their calculation are fewer compared to discounted cash flow methods. However, they are insufficient for assessing firm value, as they do not take into account all the necessary variables in determining value. For a complete analysis of a company, both modern performance measurement indicators and discounted cash flow methods are required.

## INVESTMENT FUNDS IN ROMANIA

**Copil Crina Angela**

Social Sciens Doctoral School, Faculty of Economic Sciences, University of Oradea, Oradea, Romania

[crina.copil@gmail.com](mailto:crina.copil@gmail.com)

**Abstract:** *I chose this topic because my goal was to capture in detail all aspects of the evolution of investment funds under the influence of factors leading to globalization of the banking financial market. The main motivation was that I proposed to present in an original manner the concept of investment in mutual funds by the thoroughness of the following points: the different types of investment funds from Romania, the advantages, the risks and the specific costs of the investment in mutual funds and the effects of the financial crisis on the industry of the investment funds on the national level. The financial crisis and the risk of infecting the global economy affected the taste of risk of the investors and their request for the investment fund, determining the orientation of the investors to the funds with a lower risk – the diversified funds, the funds of bonds and the monetary funds. I considered important the theoretical approach of the concept of investments in investment funds because they are a barometer of the macro economical stability, in case the economical increase is positive on the macro economical level, the investments in investments funds are increasing too. In Romania the market of the mutual funds is at an incipient level, but with potential and perspectives of development. Due to the bankruptcy of FNI in the beginning of the years 2000 and due to the absence of a clear legislation regarding the calculation of the unitary value of the net asset and the control of the activity developed by the investment funds, the development of the industry of the investment funds had to fight against the crisis of credibility generated by these events. The convergence of the Romanian economy to the European standards will attract also a modification of the structure of the financial investments of the individuals, by an increase of the investments in funds. In the world the investment funds are preferred by the investors for their advantages, respectively the investment in instruments with larger capacity, the flexibility determined by the possibility of withdrawal in any moment without losing the cumulated gain, the administration of the portfolio by the professional administrators, the access to diversified placements with small sums, the reduction of the risk by the diversification, the strict regulation and surveillance of the activity of investments administration by the authorities surveying the financial markets. In the developed countries, the placements in administered investments can reach up to 40% of the financial assets of the families, and the deposits own a percentage of 40-50% of the assets, while in Romania the percentage of the investments administered from the total financial assets of the families is under 10%, and the placements in deposits represents over 80%. I consider that the founding of the subsidiaries of assets management in Romania by the banking financial groups contributed and will contribute in a great measure in the future to the increase of the degree of knowledge and acceptance of the investment in investment funds.*

**Keywords:** investment funds, investors, efficiency, portfolio, placements, fund units.

**JEL classification:** A11, E44, G11, G12, G21

## **1. Introduction**

The globalization and the regionalization placed their imprint on the Romanian financial bank market. We can observe that similarly with the tendency of concentration, segmentation, respectively the restructuring of the bank activity on many levels in the developed countries, there are, beside the commercial banks also the specialized one, which will offer the circumstances of the bank management improvement and of the efficiency. (Opritescu 2003) The bank globalization is performed geographically and structurally, the main financial bank groups are real aggregations that include banks, insurance companies, investment funds, the so called integrated financial services. The existence of these subsidiaries will lead to the increase of the degree of coverage of the investments in investment funds.

In this paper I proposed to analyze the types of investment funds existent in Romania, the advantages and the risks related to the investment in mutual funds and the impact of the financial crisis on them. The notion of mutual fund is different from one country to another, these collective investments plans being known with the denomination of mutual funds, investments funds, administered funds or simply funds. According to the Association of the Fund Administrators the investments funds are entities that cumulate money from many people (investors in funds) money that the administrator of the fund is investing according to the declared policy of the investment of the fund, in: instruments of the monetary market, municipal or/and corporate bonds, shares bargained on the stock exchange market, and in other movable values allowed by the regulation authority (CNVM). The profits thus accomplished are redistributed by redeeming of the fund units, to the same investors.

The financial crisis determined on the world level and on the European and national level, the orientation of the investors' preferences to investment funds with a lower risk, respectively to diversified funds, of bonds and those monetary.

I consider that the improvement of the legislation in this field, the development of the pension funds, of insurances and the macro economical stability will lead to the increase of the investments funds.

## **2. Short history of the investment funds**

The investment funds became known for the investors in the period of the years 1980 – 1990 when the invested sums of money and the obtained efficiency reached very high levels. The idea of accumulating money from many persons and their professional administration by specialized persons by investing in financial instruments is much older.

The origin of the funds is uncertain – some studies sustain that the first mutual funds, closed investment funds were initiated in Nederland in 1822 by king William I; other studies affirm that the idea of creating the investments funds was given to the king William I by a Dutch trader Adriaan Van Ketwich who owned an investment company even since 1774. He sustained that the diversification is that which determined the increase of the interest to invest of the small investors who owned smaller amounts

of money. The name of the investment fund created by Ketwich, *Eendragt Maakt Magt* is translated by "the unity creates power".

The first closed fund of investments created in USA in 1893 was Boston Personal Property Trust. The launching of the Alexander investments fund in Philadelphia in 1907 was a large step in the history of the modern mutual funds. In 1928 was launched the Wellington investments fund, the first mutual fund that invested in shares and bonds. The financial crisis from 1929 determined the reversal of the dynamics of the investment funds, the closed funds of investments being liquidated in a great measure, only a few of the opened investment funds succeeding to survive. The expansion of the industry of mutual funds determined also the creating/improving of the legislative background specific for the regulation of the conditions regarding the registration of new mutual funds, the protection of the investors, the delivery of information to them with the help of the funds prospects. According to the historical information regarding the mutual funds, they became popular in the last 20 years.

### **3. The presentation of the types of investment funds**

According to the Erste Asset Management a fund is actually a portfolio of financial instruments administered by experts (administrators) who respect the legal requests regarding the diversification of the risks. By the aggregation of the investments performed by the investors, the fund disposes of enough capital to be able to invest in diversity of financial instruments on some markets. In case he would act individually, the investors would find a series of difficulties or would need large sums of money in order to obtain the results offered by the fund. The investors own fund units that represent titles of participation in the fund assets.

Every fund invests depending on its own policy of investments in different currencies, in financial instruments from different geographical regions or belonging to some sectors of activity, the funds promoted with different name considering the geographical regions where they invest (Emerging Europe) or some activity sectors, (ex. Technology). It was found that depending on the country and the risk of the currency in which the fund invests, there is a preference for the funds that invest in the local currency or in the financial instruments on the internal market. The preference of the investors for some investment funds is established depending on the investment policy of the funds, their past performances, the commissions related to the investment in funds, etc. Some funds of investment are addressing to some sophisticated investors, others are addressing to those from the Private Banking category.

The investment funds can be, depending on the class of assets in which they invest – monetary funds, bond funds, diversified funds and share funds; each of these funds are associated different degrees of risk.

- *The monetary funds* invest in instruments of the monetary market. The objective of these funds is to protect the invested sum of money and to assure an income. These funds are addressing the conservatory investors, with a decreased risk profile, the average period of the placements is of 1 year.

- *The bond funds* invest in municipal, corporatist bonds or in state titles. These funds have a strategy of investments based more on obtaining the income than on the increase of the investment. The bond funds are addressing to the investors that want

to obtain performances of the investment higher than those related to the investment in instruments of the monetary market.

- *The diversified funds* invest in shares, bonds and sometimes in instruments of the monetary market. These funds have a strategy of investments based on income, increase and stability and are addressing the investors that want to obtain an income but also a potential increase on a long term higher than in the case of the bond funds.

- *The share funds* invest in shares. These funds have a strategy of investments based on the increase.

In Romania, the investment funds are found in the following forms:

- *Organizations of collective placement in movable values* (OPCVM) in the form of open investment funds (open end funds; UCITS)

- *Other types of organizations of collective placement* (AOPC) in the form of closed funds of investments and companies of financial investment (SIF) whose shares are bargained at BVB (closed end funds; non UCITS).

Between the open funds of investment and those closed the main difference consists of the way the issuance of the fund unit is organized.

The open funds have a permanent issuance of fund units as opposed to those closed which don't have a continuous issuance and are addressed to a limited number of investors. The open fund of investments is a civil company, without a juridical personality, that collects the money available from investors by continuous issuance of fund units, invests in financial instruments and distributes the income to its investors, in the moment of the redemption of the fund units. Not having a juridical personality, the open funds of investments are administered by a company of investment administration (SAI). A company of investment administration can manage one or more mutual funds.

To the open funds can permanently be subscribed investors, new ones and those well established in the fund. In the same time, some investors can withdraw completely or can redeem a part of the number of fund units owned.

In case of a closed fund of investments, is issued a limited number of fund units during an initial public offer (IPO). Afterwards, these units are transitioned directly or to the share market by the fund manager. If the request for units is great, they can be traded with a value greater than the value of a fund unit (are traded with bonus). Similarly, if the request for units is reduced, they can be traded with a value smaller than the value of the fund units (are traded with discount).

### **3.1 The method of functioning of the mutual funds**

The present value of the assets of the fund represents the total assets of the fund. If these total assets are subtracted the present expenses of functioning of the fund it is obtained the total of net assets. The unitary value of the net assets (VUAN) or the value of the fund unit is obtained dividing the total net assets to the number of fund units. The value of the net assets, the unitary value of the net assets and the number of investors is calculated daily by the company administering the investment and is certified by the depositary. The value of the net assets and the unitary value of the net assets will be published by the company administering the investments daily for each working day in newspapers in the financial field and on the website of the administration company and will be posed daily for each working day at the registered office of the company of investments administration and at the registered office of the agents distributing the fund units. The list of the distributor agents can be accessed on the website of the company of investment administration.

### 3.2 The advantages of the investment in an investment fund

The advantages of the investment in mutual funds are the following:

- The investment funds represent diversified portfolios of financial instruments, *the related risk being smaller* than the risk associated to each financial instrument in part. As a consequence a diversified portfolio can obtain good results even if some shares register losses.
- The legal structure and the strict regulations that govern the investment funds offer a *very large protection* against the fraud or the illegal financial practices.
- Each investor has at his disposal the prospect of the fund, which includes all the document that are used for the functioning of the fund, assuring thus a great degree of *transparency*, can be accessed in any moment the website of the fund.
- With an *investment relatively small*, the investors can participate to investments on financial markets that are difficult to be accessed by the small investor.
- the mutual funds pay *smaller commissions of trading* than the individual investors. The costs of trading more reduced are translated in better performances of the investments.
- The open funds of investments offer *more liquidity* than the other financial instruments. The investors have the possibility to exit the fund investment in any moment, by the redeeming of the fund units by the fund. The value of the fund unit is calculated daily, they can be purchased and sold in any moment by filling in a simple form. The investment funds are obligated by law to accept any redemption of the issued titles.
- *The professional management* – a specialized team takes the decisions of purchase and sale, on the basis of some detailed analysis. More over while the conditions of the market are changing, the management of the fund is restructuring the portfolio, so that the financial objectives can be reached, the portfolio is monitored and optimized permanently.
- *Protecting the investments* – the investment funds and the administration company of these funds need to respect the laws and the strict rules imposed by the National Commission of the Movable Values..

### 3.3 The risks associated to the investment in investment funds

The investments in investment funds are not guaranteed by the state and the investment funds don't participate to the fund of guaranteeing the bank deposits. The investment in a mutual fund can increase or decrease depending on the evolution of the price of the financial instrument in which the fund invests. The past performances of the investment fund don't represent a guarantee of the future accomplishments. The mutual funds invest in financial instruments that presuppose a certain degree of risk. This degree of risk related to financial instruments is different depending on the expected efficiency. The obtaining of performance is in a close relationship with the assumed degree of risk, thus, for a decreased level of risk, the level of expected performance is decreased and for an increased level of risk the expected performance is increased. The clients have to know the risk they are exposed when they choose an investment fund. For example when they decide to invest in instruments with fixed income they involve a decreased degree of risk but also a reduced expected efficiency. The investment in shares implies an increased risk but also an increased expected efficiency. The managers of funds have to respect the rules of the fund which are approved by the National Commission of the Movable

Values and the effective legal provisions, also the administrator has the possibility to administer the assets and won't access the money of the investors which are controlled by the depositary.

### 3.4 The investment funds in Romania

The market of the mutual funds from our country is still at a low level comparing to other countries from The European Union but with an increased potential of development. The lack of trust in the investment funds in the last 12 years was due to the National Fund of Investments, which prejudiced a great part of the investors of that time. This was due also to the precarious legislation regarding the calculation of the unitary value of the net assets and the control of the activity developed by the investment funds. In this period it had to be done a hard work for the regaining of the trust lost, the legislation in this field was improved so that the investment funds began to become "a world to be conquered", as the specialists from Erste Asset Management say.

This legislation was aligned to the European legislative regulations. The way the investors are protected in the present legislation and all the links related to the launch of such a product, shows clearly that the bankruptcy of a mutual fund is not possible. For sure the value of a mutual fund can decrease according to the evolution of the market but the possibility of a fraud or the major losses are excluded.

It was observed in some countries from Central Europe and Eastern Europe that in the first place the economical stability correlated with a rate of inflation reduced lead to the development of the investment fund market. Also the appearance of some pension funds, of insurance, that want to place the sums of money for long periods of time with better efficiency than for the bank deposits lead to the increase of the degree of intrusion of these funds on the market.

We can say that the secrets of the investment funds would be the great force of negotiation of the interest including for the deposits of large sums of money, and the better efficiency obtained by the professionals.

Since 2000 and until the present the mutual funds from Romania attracted over 245.000 investors, reaching to a record level. This number is important more over because it was reached in the conditions of the financial crisis.

Year	Investors	Funds	Assets (mil.lei)
2005	71.021	23	339
2006	78.380	32	633
2007	82.458	41	954
2008	90.694	52	940
2009	164.446	51	3.350
2010	221.862	57	5.488
2011	233.777	61	6.781
2012	241.368	63	8.811

Figure 1: The evolution of the open fund investments market 2005-2012  
Source: The report of the association of the fund administrators

We can observe that in the last eight years the number of the investment funds and the number of investors was tripled and the invested assets increased from 339 mil to 8.811 mil. Ron; that shows that more Romanians chose beside the convenience of the deposits the investment funds as an alternative that offers them a better efficiency. In the period of financial crisis were preferred the funds that have a lower degree of risk, are liquid and offer better efficiency.

In Romania, beside the local mutual funds, namely the investment funds belonging to the organizations of collective placement from Romania, are distributed also fund units belonging to the organizations of collective placement from members states from The European Union.

The organizations of local collective placement in movable values (OPCVM) were consolidated beginning with the year 2009 the role of alternative solution of saving, attracting publicly the significant financial resources from the individuals and juridical persons. Thus, after an easy repulsion in the previous year, the industry of the investment funds registered beginning with the year 2009 a significant positive evolution, in the level of the number of investors, and in the level of the net assets in the administration.

In 2009, the number of investors in open funds of investments (FDI) AAF members (The Association of the Fund Administrators from Romania) increased with 81% comparing to 2008 (164.446 investors), especially due to the individuals investors, the total number of investors in the open investment funds and AOPC (Other organizations of collective placement) reaching to over 250.000, and in 2012 the total number of investors was of 335.000. The value of the net assets was influenced positively by the recovery of the quotations of the listed share and by the significant increase of the number of investors and their volume of investments. The sum of net assets of the open fund investments at the end of 2009 was of 3,35 billion RON, 256% over the level registered at the end of 2008, and in 2012 of 8,81 billion Ron. The first 5 administrators of funds registered the following total market shares on 31.12.2009: Erste Asset Management – 43,08%, Raiffeisen Asset Management – 30,23%, BRD Asset Management – 8,49%, BT Asset Management – 4,86% and OTP Asset Management – 3,28%. On 31 January 2013 the market shares were the following: Erste Asset Management – 37,48%, Raiffeisen Asset Management – 33,37%, ING Asset Management Bucuresti-12,43% and BRD Asset Management – 7,41%. It can be observed that Erste Asset Management is the financial group with the largest market share in 2009 and in the present.

In the table presented below is presented the evolution of the investment funds (open and closed) in December 2012 comparing with the previous month and the beginning of 2012.

31.12.2012	Open funds of investments (OPCVM)							Total	
	Monetary	Bonds	Diversified	Shares	Funds of funds	Others	Total	Closed funds AOPC	OPCVM funds and AOPC
Number of funds	1	27	23	49	1	16	117	21	138
Percentage in total assets OPCVM (%)	0,2	49,4	2,6	5,7	0,1	42	100		
Assets net (mil. Lei)	17,5	5.059	263,2	577,4	9,8	4286,2	10.790,4	420,5	11.210,9
% in the report month	-2,0	2,9	2,8	12	2,3	0,6	5,5	1,9	7,4
% in year 2012	-99,5	174,5	7,8	16,8	9,0	234,8	45,75	60,9	106,6
Subscriptions monthly (mil. Lei)	1688,1,1	1816,7	61,3	88,7	0,1	2378,5	6026	258,6	6284,6
Redemptions monthly (mil. Lei)	1233,9	1027,1	72,8	96,6	0,0	2055,0	4485,5	116,5	4602
Subscriptions net monthly (mil. Lei)	454,2	782,2	-11,5	-7,9	0,1	323,5	1540,5	142,1	1682,6
Number of investors	60	110392	51281	11.352	6	68.097	241368	91.684	333052

Figure 2. – The evolution of the investment funds (open and closed) in December 2012 comparing with the previous month and the beginning of 2012

Source : Association of the Fund Administrators

From the analysis of the data presented in this table we can see that at the end of December 2012, the number of investment funds was 138, of which 117 open funds of investment and 21 closed funds of investment. From the point of view of the volume of administered assets by the investment funds, the greatest percentage was owned by the bond funds - 49,4%. The great percentage of the assets administered by the bond funds is due to the aversion to risk caused by the financial crisis that oriented the interest of the investors to placements with a reduced risk.

On 31.12.2012, the total volume of assets of the investment funds had a total of 11.210,9 mil. RON of which 10.7940, mil. RON in open funds of investment and 420,5 mil. RON in closed funds of investment. Comparing to the beginning of 2012, the volume of assets of the open funds was of 333.052 on the date of 31.12.2012, of which 91.684 investors in closed funds of investment and 241.368 investors in closed funds of investment.

In December 2012, we can observe that the assets of the monetary assets decreased with 99,5%, reaching 454,2 mil. RON, the assets of the bond funds increased in December 2012 with 174,5% comparing to the beginning of the year, reaching to 5.059 mil. RON. In December 2012, these funds attracted net subscriptions of 782,2 mil. RON. The share funds registered an increase with 16,8% in 2012 the assets were of 577,4 mil. RON.

The assets of the fund funds registered an increase of 2,3% in December 2012 comparing to the previous month and an increase of 9% from the beginning of the year, having assets of 9,8 mil. RON.

The assets of the funds from the category "Other" increased with 0,6% in December 2012 comparing to the previous month, reaching to 4286,2 mil. RON. On the other side, the assets of the closed funds had in December 2012 a value of 420,5 mil. RON, increasing with 1,9% comparing to the previous month and 60,9% from the beginning of the year.

#### **4. In conclusion**

Regarding the conclusions of the research I consider that the present global economic and financial situation presents a high degree of disequilibrium due to the financial crisis. In this context, I consider that the investors will give a greater attention to the way the portfolio of investment are structured with a stress on their expectance, the understanding of the efficiency-risk correlation, orienting thus to investments with a lower degree of risk. The new philosophy of investments based on the behavior of the clients represents a major and global tendency from the economic and social point of view that will create important opportunities for the increase and transforming of the industry of investment funds.

After 2008 the investors structured their portfolio so that the risk would be minimum, increased the bond funds comparing to the deposits, in general, oriented their philosophy on investments from performance to risk and protection of the assets. The management of the risk has to be calculated actively.

The trust in the investment funds was regained step by step, we could say at this moment that more investors are considering the investment funds due to some upper efficiencies of the deposits, only at Erste Asset Management the number of investors was over 100.000 Romanians. We could say that they understood that one of the secrets of the success in investments is to widen the horizon beyond the convenience of bank deposits.

The increase of the segment of the investment funds from the last years is connected mainly by factors like the investment opportunities, the strategies of the financial bank groups relate to the distribution of the investment funds, the increase of the degree of financial bank education of the population.

I am confident in the evolution of the investment funds considering that the Romanian economical and bank environment is in a continuous dynamic with influences on the clients and on the economy, it can't remain isolated from the transformations that are produced on the international level in the context of globalization. The dynamic development of the investment funds caused by a larger range of financial instruments available and of the interesting performances brought by the investment funds until the present allows me to estimate that also in Romania the placements in administered investments will be close to 40% as in the developed countries, and the percentage of the bank deposits will reach to 40-50%. Also the consolidation of

the macro-economical stability and the decrease of the inflation will contribute to the increase of the industry of investment funds.

The perspectives of the capital market, the familiarization with such alternatives to the classic instruments of saving are some factors that would make them the most important ways of investment from the financial market.

# CORPORATE GOVERNANCE COMMITTEES IN EUROPEAN UNION EMERGING ECONOMIES

**Dumitrașcu Mihaela, Gajevszky Andra**

*Accounting Department, Faculty of Accounting and Management Informatics System*

*University of Economic Studies, Bucharest, Romania*

*red\_mille\_ro@yahoo.com*

*gajevszkyandra@yahoo.com*

**Abstract** *The aim of this research is to analyze the support committees of European Union emerging economies. The importance of good corporate governance is vital for an organization, especially in the emerging markets, fact that leads to a several perceived improvements of the entity, while being more trustable, open and transparent in relationship with all its stakeholders. In our demarche we started by choosing the emerging economies from European Union, which lead us to a sample consisting of the companies listed on Bucharest Stock Exchange, Sofia Stock Exchange, Warsaw Stock Exchange, Prague Stock Exchange, Budapest Stock Exchange, without taking into consideration a specific tier. In order to have a heterogeneous sample, we did eliminate the financial institutions from our research. This study is developed at European Union level and takes into consideration the following indices: BET® BUCHAREST EXCHANGE TRADING (Romania), SOFIX (Bulgaria), WIG 20 (Poland), PX (Czech Republic), BUX The Share Index of the Budapest Stock Exchange Co. Ltd. (Hungary). The data are extracted from the Annual Reports, Corporate Governance Codes, Comply or Explain Statement or the websites of the listed companies, from period 2007 - 2011. We choose this period, because we wanted to see the evolution of the corporate governance committees' implementation from the period when the last countries from our sample joined the European Union since nowadays. Our conclusion is that we can not discuss about good corporate governance practices. Even so, we can observe from our investigation that the trend in this regard is encouraging. Like future research, we thought at developing our study by comparing the emerging economies from European Union with those outside this area. It is an interesting field of investigation, as every country has different regulations.*

**Keywords:** corporate governance, committees, emerging economies, transparency

**JEL Classification:** G30, G34

## 1. Introduction and Literature Review

*Corporate governance* is a topic which started to gain an increasing interest not only at the academic level, but also at the practical one, and nowadays the importance of good corporate governance practices is perceived widely as a vital mechanism for a healthy entity. The issue related to the **committees** is debated at global level. The need for this study is given by the fact that we must know which companies have the best corporate governance practices. However it is a little bit hard to develop such a

study, seeing that there are many Corporate Governance Codes, Standards, Laws worldwide and a convergence of all of them is quite impossible.

In 1992, after the corporate scandals that took place, was introduced the first Code of Corporate Governance, The Cadbury Code, developed by the London Stock Exchange, in United Kingdom. There are also international principles and here we can mention the OECD Principles, which functions as an orientation guide for both OECD member countries and also for those who are not members of OECD (OECD, 2004).

There is a plenty of definitions regarding corporate governance. So far, the most important is the one of Sir Adrian Cadbury, which said that “corporate governance is the system by which companies are directed and controlled”.

There are many studies regarding the corporate governance committees. Here we can mention a study which examines the remuneration committees for a sample of 220 companies from UK. The results reveal the fact that 30 per cent of them have such a committee (Main and Johnston, 1993). Some authors explore the interest on the board supervision, corporate governance committees, on a sample of Fortune Global 250 companies and the results shows that the detailed disclosures are not common. (Kolk, 2006). Other article shows the divergences between the corporate governance committees in France, the Netherlands and the UK. (Karel 2002)

There is an interest to develop a study about committees, for both researchers and companies.

According to Bucharest Stock Exchange, the Audit Committee and the internal auditor should regularly provide the members of the board with information. According to Rec. 27 of Bucharest Stock Exchange: The board should establish an audit committee, from among its members, to assist in the discharge of its responsibilities in the areas of financial reporting, internal control and risk management. Until an audit committee has been set up, the board should deal with these tasks and responsibilities, in close collaboration with the internal and external auditors; to this purpose the Board should meet at least twice a year with the internal and external auditors to discuss issues connected with financial reporting, internal control and risk management. Rec. 28 : The board or, where relevant, the audit committee, should regularly examine the effectiveness of the financial reporting, internal control and risk management system adopted by the company; it should make sure that the audits carried out and the subsequent audit reports conform to the audit plan approved by the board or the audit committee. Rec. 29 : The audit committee should be composed exclusively of non-executive directors; it should contain a sufficient number of independent directors Rec. 30 : The audit committee should meet as often as it deems necessary, but at least twice a year, when it will deal with the half-yearly and yearly results and their disclosure to the shareholders and the public. Rec. 31 : The audit committee should assist the board in monitoring the reliability and integrity of the financial information provided by the company, in particular by reviewing the relevance and consistency of the accounting standards applied by the company (including the consolidation criteria). Rec. 32 : The audit committee should be informed of the external auditor’s work program and receive a report from the auditor describing all existing relationships between the external auditor on the one hand and the company and its group on the other hand. The audit committee should make recommendations to the board regarding the selection, appointment, reappointment and removal of the external auditor and, in addition, the terms and conditions of their remuneration. It should monitor the independence and

objectivity of the external auditor, in particular by monitoring the rotation of the partners of the audit firm. According to Bulgarian Code for Corporate Governance, Corporate boards, assisted by the Audit Committee and in accordance with the established professional standards and requirements, present in writing at the General Shareholder Meeting a motivated proposal for the selection of an external auditor. The principle of rotation should be applied in selecting and appointing an external auditor. The company should develop and implement an internal control system which should also ensure the early identification of any material risks the company may face and to effectively manage those risks. Such system should ensure also the effective functioning of the reporting and disclosure of information systems. Budapest Stock Exchange stipulates that the audit committee will usually have 3 to 5 members, mainly or wholly independent directors, who will meet at least four times a year.

According to Article 6 of the Corporate Governance Code of Bucharest Stock Exchange, the Board should establish a Remuneration Committee from among its members. The Remuneration Committee should be composed exclusively of non-executive directors and it should contain a sufficient number of independent directors. According to Rec. 21 of Bucharest Stock Exchange: The board should establish a Remuneration Committee from among its members, to assist in formulating a remuneration policy for directors and managers and it should define the committee's internal regulations. Until a Remuneration Committee has been set up, the board should deal with these tasks and responsibilities at least once a year. The remuneration policy shall be subject to AGM approval directors; it should contain a sufficient number of independent directors. The board should ensure that the Remuneration Committee has access to the necessary skills to effectively fulfill its role. The Remuneration Committee may seek assistance from external experts for the fulfillment of its duties, on issuer's account. Rec. 23 : The Remuneration Committee should submit proposals to the board regarding the remuneration of directors and managers, ensuring that these proposals are in accordance with the remuneration policy adopted by the company. The remuneration of non-executive directors should be proportional to their responsibilities and the time devoted to their functions. directors; it should contain a sufficient number of independent directors. The board should ensure that the remuneration committee has access to the necessary skills to effectively fulfill its role. The remuneration committee may seek assistance from external experts for the fulfillment of its duties, on issuer's account. Rec. 23 : The remuneration committee should submit proposals to the board regarding the remuneration of directors and managers, ensuring that these proposals are in accordance with the remuneration policy adopted by the company. The remuneration of non-executive directors should be proportional to their responsibilities and the time devoted to their functions. Rec. 24 : The company should disclose its remuneration policy in its CG Charter. The total amount of direct and indirect remuneration received by directors and executive managers by virtue of their position should be disclosed in the annual report; a distinction should be made between the fixed and the variable components of this remuneration. Regarding the Remuneration Committee, the Corporate Governance Recommendations of Budapest Stock Exchange by the general meeting (or on the basis of authorisation by the general meeting, the Managing Body) should set up a Remuneration Committee from the members of the Managing Body, which assists in outlining the principles of the remuneration of the members of the Managing Body, the

Supervisory Board and the executive management. Related to the conditions of non-executive and independent members of this committee, it is suggested that the Remuneration Committee consists exclusively of non-executive members of the Managing Body (2005/162/EC App. I. 3.1.2.) and the majority of the members of the Remuneration Committee should be independent (2005/162/EC App. I. 3.1.2.) Corporate Governance Recommendations prepared by Corporate Governance Committee of the Budapest Stock Exchange Company Limited by Shares: R 3.4.1. The general meeting (or on the basis of authorization by the general meeting, the Managing Body) should set up a Remuneration Committee from the members of the Managing Body, which assists in outlining the principles of the remuneration of the members of the Managing Body, the Supervisory Board and the executive management. R 3.4.2. The Remuneration Committee should make a proposal for the system of remuneration of the Managing Body, the Supervisory Board and the executive management (individual level and structure of fees), and carry out a review, ensuring adequate structure and transparency. (2005/162/EC App. I. 3.2.) No member of the Managing Body may participate in formulating a suggestion on his own remuneration. R 3.4.3. The Remuneration Committee should prepare proposal packages for the Managing Body, to be discussed and approved, in the case of the executive management, by the Managing Body, in the case of the Managing Body, by the general meeting. It is the task of the Committee to exercise control over the system of share options, cost reimbursements and allowances (agreements on pensions, severance pay) contained in the remuneration of the Board members and the members of the executive management. (2005/162/EC App. I. 3.2.) E When making its proposals, the Remuneration Committee takes into consideration the performance of the company and the individual, in the case of Board members and members of the executive management, other possibilities for fulfilling the given position, as well as remuneration applied by other companies. The Remuneration Committee formulates remuneration guidelines and benchmarks and it controls their implementation. R 3.4.4. In addition to remuneration guidelines and proposals on the remuneration of given individuals, the Remuneration Committee should also deal with the terms of agreements concluded with members of the executive management, and ascertain whether the company has fulfilled its publication obligations regarding issues of remuneration. (2005/162/EC App. I. 3.2.) S 3.4.5. The Remuneration Committee should prepare a Remuneration Statement to be published annually. ("Remuneration Statement" – 4.1.11.) (2005/162/EC App. I. 3.2.) S 3.4.6. It is suggested that the Remuneration Committee consists exclusively of non-executive members of the Managing Body. (2005/162/EC App. I. 3.1.2.) R 3.4.7. The majority of the members of the Remuneration Committee should be independent. (2005/162/EC App. I. 3.1.2.) R 3.5.1. When setting up the committees, the Managing Body may decide that the duties of the Nomination Committee and the Remuneration Committee will be executed by one (merged board) committee. In this case, an explanation should be given as to the causes of the decision, and it should be indicated how, according to the Managing Body, the committees, with a reduced number of members, will be able to achieve the general goals of two (remuneration and nomination) committees. (2005/162/EC 7.1.) R 3.5.2. In the case of a small number of members, the Managing Body may carry out the duties of the Nomination and Remuneration Committees, if it meets the requirements regarding the composition of the given committee and provides adequate information on this. (2005/162/EC 7.2.) In order to assist directors to properly shoulder their

responsibilities and be in a position to inform shareholders knowledgeably about activities of their company it is recommended that Boards include the adoption of committees which review the audit, nomination and remuneration functions of the company. The establishment and functioning of each of these three committees should follow an unemotional style and consequently it is better that they are composed mainly, if not wholly, by independent directors. The Remuneration Committee usually has 3 to 5 members, mainly or wholly independent directors, who meet annually but may need ad hoc sessions as well. Code of Best Practices of Warsaw Stock Exchange has no information related to Remuneration Committee. The recommendations of OECD Principles from 2004 for Prague Stock Exchange: the Board shall appoint Nomination Committee and Remuneration Committee among from its members.

In the principle X of Article 5 of the Corporate Governance Code of Bucharest Stock Exchange it is stated that the Board of Directors shall evaluate whether to establish among its members a Nomination Committee made up, mainly, of independent directors. According to Bucharest Stock Exchange, The Board of Directors shall evaluate whether to establish among its members a Nomination Committee made up, mainly, of independent directors. According to Rec. 19 of Bucharest Stock Exchange: Where established, the Nomination Committee should lead the process for board appointments and make recommendations to the board to propose candidates for the position of director. Rec. 20 : The Nomination Committee should evaluate the balance of skills, knowledge and experience on the board and, in the light of this evaluation, prepare a description of the role and capabilities required for a particular appointment. In the third chapter of the Corporate Governance Recommendations of Budapest Stock Exchange it is stated that the general meeting (or on the basis of authorisation by the general meeting, the Managing Body) should set up a Nomination Committee from the members of the Managing Body, which assists in selecting members for the Managing Body, the Supervisory Board, and the Chief Executive Officer. In the same Recommendations it is suggested that the majority of the members of the Nomination Committee are independent. (2005/162/EC App. I. 2.1.2.) R 3.3.2. The Nomination Committee should ensure the preparation of personnel changes with the aim that the replacement of a Managing Body member leaving due to retirement, resignation or any other reason, or the succession of members of the executive management is carried out smoothly, with the company's work continuing uninterrupted. The Nomination Committee examines the practice of the Managing Body for selecting and appointing members of the executive management, assesses the performance of members of the Managing Body, the Supervisory Board, and the executive management (and the suitability of candidates). The Nomination Committee examines all suggestions relating to the nomination of Board members which are submitted by the shareholders or the Managing Body. E The Nomination Committee's main task is to prepare informed and objective suggestions to the shareholders on the nomination for membership of the Managing Body and the Supervisory Board (appointment, dismissal). The purpose of the Committee's operation is to ensure that members of the Managing Body and the Supervisory Board possess adequate qualifications and professional experience to perform their duties in the best interest of shareholders. As part of company strategy those persons who have the capacity to substitute or replace appointed managers and members of the Managing Body shall be specified. Preparation for personnel changes also includes the identification of employees with

outstanding performance, and the planning of their careers within the company. For the sake of the above, when judging the suitability of candidates, the Nomination Committee should not only take into consideration business and personal relations, but also examine the candidate's competence, professional ability, and estimate whether the candidate is capable of devoting enough time to carry out his duties as a Board member. (2005/162/EC App. I. 2.2.) It is suggested that the Nomination Committee prepares an evaluation at least once a year for the Chairman of the Managing Body on the operation of the Managing Body, and the work and adequacy of the members of the Managing Body. S 3.3.4. It is suggested that the majority of the members of the Nomination Committee are independent. (2005/162/EC App. I. 2.1.2.) S 3.3.5. The Nomination Committee's rules of procedure should give details of the criteria used for the appraisal of nominees. In addition to the provisions of current Hungarian laws and regulations, these criteria should cover membership of the Boards' and committees' of other companies, the degree of the nominees' independence, and their experience acquired. The Nomination Committee usually consists of 3 to 5 members, mainly or wholly independent directors, who meet as required. Code of Best Practices of Warsaw Stock Exchange has no information related to Nomination Committee. The recommendations of OECD Principles from 2004 for Prague Stock Exchange state that the Board shall appoint Nomination Committee and Remuneration Committee among from its members.

## **2. Sample Selection and Methodology**

In our demarche we start from choosing the emerging economies from European Union. So, our sample is consisting of the companies listed on Bucharest Stock Exchange, Sofia Stock Exchange, Warsaw Stock Exchange, Prague Stock Exchange, Budapest Stock Exchange, no matter what tier. Because we want to have a heterogeneous sample, we have eliminated the financial institutions from our research. This study is developed at European Union level and takes into consideration some indices, like: BET® BUCHAREST EXCHANGE TRADING (Romania), SOFIX (Bulgaria), WIG 20 (Poland), PX (Czech Republic), BUX The Share Index of the Budapest Stock Exchange Co. Ltd. (Hungary). BET, the first index developed by BVB, is the reference index for the Bucharest Stock Exchange (BVB) market. BET is a free float weighted capitalization index of the most liquid 10 companies listed on the BVB regulated market. SOFIX is an index based on the market capitalization of the included issues of common shares, adjusted with the free-float of each of them. WIG20 index has been calculated since April 16, 1994 based on the value of portfolio with shares in 20 major and most liquid companies in the WSE Main List. The initial value of WIG20 index was 1000 points. It is an price index and thus when it is calculated it accounts only for prices of underlying shares whereas dividend income is excluded. The WIG20 index may not include more than 5 companies from a single exchange sector. PX is the Price Index of blue chip issues. The BUX index is the official index of blue-chip shares listed on the Budapest Stock Exchange Ltd. It is calculated in real time by the BSE every five seconds based on the actual market prices of a basket of shares. The index shows the average price changing of the shares with the biggest market value and turnover in the equity section. Hereby this is the most important index number of the exchange trends. The data are extracted from the Annual Reports, Corporate Governance Codes, Comply

or Explain Statement or the websites of the listed companies, from period 2007-2011. We choose this period, because we wanted to see the evolution of the corporate governance committees' implementation from the period when the last countries from our sample joined the European Union since nowadays. There are 44 companies in our sample. The period analyzed is between 2007- 2011. We did not excluded the banks and other financial institutions from our sample, even if they have special regulations, but we must excluded the companies that do not have the complete information or that ones that do not have published it. So, our final sample consists of 37 companies.

**Table 1** The Sample Selection

Source: The authors (based on the research)

We purpose in our demarche to analyze through the present study up to 35 criteria: 11 criteria (for the Audit Committee), 8 criteria (for the Remuneration Committee), 8 criteria (for the Nomination Committee), 8 criteria (for the Compensation Committee). The paper is organized as follow: it has an introduction, a section which consists in the literature review regarding the corporate governance and corporate governance committees, a section that describes the sample selection and the methodology aspects, a section that disclose the aspects related to our study, its components and the section that draws some conclusions.

### 3. **Research and Results Regarding Committees**

#### *Prague Stock Exchange*

From the eleven companies out of our sample, eight (72%) have an Audit Committee through the analyzed period, with the minimum of seven companies in year 2008 and the maximum of nine companies in 2011. Between 2007-2010, only three companies (27%) had a Nomination Committee and a Remuneration Committee, while in 2011 the number of companies having these two committees increased with 10 %. Related to the Compensation Committee, there was a single company that has established it, which means that only one of the ten analyzed companies considered this committee to be necessary.

#### *Budapest Stock Exchange*

Out of the six companies of our sample, all of them had an Audit Committee through the analyzed period, fact that leads us to the conclusion that for the companies listed on the Budapest Stock Exchange, the establishment of an Audit Committee is very relevant. Related to the Nomination Committee, only one company out of the six

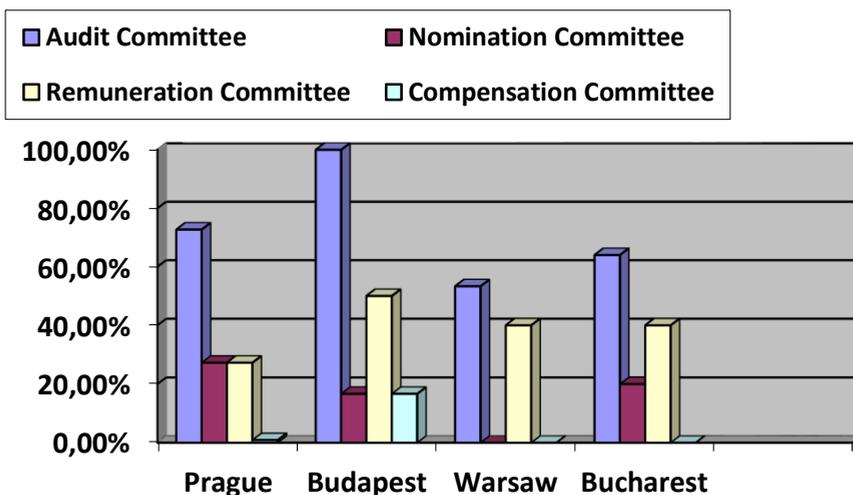

ones had established this support committee, while half of them had established a Remuneration Committee. When analyzing the existence of the Compensation Committee, we have discovered that only one company has established this consultative committee.

*Warsaw Stock Exchange*

From the fifteen companies of the Warsaw Stock Exchange sample, in medium, eight companies (53,33%) had an Audit Committee through 2007-2011, with six companies (40%) in 2007 and eleven (73,33%) in 2011. None of the studied companies had an independent Nomination Committee, but three of them (20%) had a Nomination and Remuneration Committee. Related to the Remuneration Committee, in medium, six companies (40%) of the selected sample had established this committee, with a minimum number of four companies in 2007 and the maximum number of seven companies in 2010 and 2011. None of the companies had through the analyzed period a Compensation Committee.

*Bucharest Stock Exchange*

Out of the five companies which formed the sample, in medium, 3.2 had established an Audit Committee, leading to a percentage of 64 % companies which had an Audit Committee in the analyzed period. Through 2007-2011, only one company (20%) out of the five ones that formed the sample for Bucharest Stock Exchange had a Nomination Committee, while two companies (40%) had established a Remuneration Committee. As in the case of Warsaw Stock Exchange sample, none of the selected companies had a Compensation Committee.

**Figure 1** The presence of the four Committees in the selected sample

As it can be seen in the figure above, the companies listed on the Budapest Stock Exchange have in proportion of 100% an Audit Committee, being followed by those from Prague, Warsaw and finally Bucharest Stock Exchanges. Analyzing the existence of the Nomination Committee, we can observe that the highest number of

Source : The Authors

companies which have established this committee is from Prague Stock Exchange, followed by Budapest, Bucharest and last Warsaw companies. The Budapest Stock Exchange sample of companies comprise the highest number of entities which have a Remuneration Committee, while the sample from Prague Stock Exchange scores the lowest in terms of companies which have established a Remuneration Committee. Again the sample from the Budapest Stock Exchange scores the highest in terms of companies which have a Compensation Committee, being closely followed by Prague sample, while the companies listed on the Warsaw and Bucharest Stock Exchanges did not establish a Compensation Committee.

#### *Prague Stock Exchange*

In terms of Audit Committee size, the number of members oscillated from 3.11 in 2011 to 3.28 in 2008, the medium number of members for the 2007-2011 period being 3.21. Related to the Nomination Committee size, between 2007-2010, the number of members staid constant at 3.66, reaching 3.5 in 2011 with a medium number of 3.63. The members of the Remuneration Committee remained constant along the analyzed period, with the number of 3 members. In terms of Compensation Committee size, the number of members composing this committee was 3.

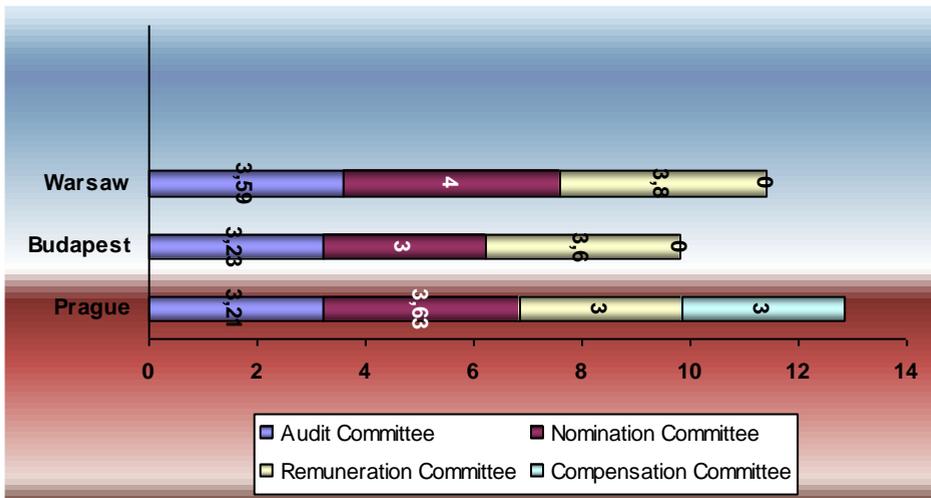

#### *Budapest Stock Exchange*

Between 2007-2009, the number of Audit Committee members reached the value of 3.17, increasing both in 2010 and 2011 at 3.33 members, with a medium number of 3.23 members along the analyzed period. The Nomination Committee size remained constant along 2007-2011 with a number of 3 members. The Remuneration Committee had in 2007 3.33 members, increasing until it reached 3.67 members for the next analyzed years, leading to a 3.6 medium number of its members.

#### *Warsaw Stock Exchange*

When taking into account the Audit Committee size, it can be stated that the maximum number of members was 4 in 2007 with the lowest number of 3.5 members in 2010. Still, the medium number of Audit Committee members was 3.59, while the medium number of the Nomination Committee size was 4 along the period 2007-2011. The medium Remuneration Committee size was 3.8 members with 3.75 members in 2007 and 2008, increasing slowly to 4 members in the next two years.

**Figure 2** The four Committees size

Source : The Authors

Analyzing the graphic above, the companies listed on the *Warsaw Stock Exchange* have the highest number of Audit Committee members, as well as Nomination Committee members and Remuneration Committee.

On *Prague Stock Exchange* company sample, one of the analyzed companies has a Nomination and Remuneration Committee consisting of 5 members, out of which 3 are non-executive throughout 2007-2011. In 2011, another company has established a Nomination Committee composed of 3 members, 2 non executive, 1 independent and independent chairman. For the other companies which had a Nomination Committee, there were no information available related to non executive and independent members. Regarding the Remuneration Committee, there was a company with a Remuneration Committee consisting of 3 members, out of which 2 were non executive and independent without independent Chairman.

On *Budapest Stock Exchange* company sample, one company has a Corporate Governance and Nomination Committee consisting of 4 members, all of them being non executive and independent, with independent chairman. For the rest of the companies, there were no information available related to non executive and independent members.

On *Warsaw Stock Exchange*, one company had a Remuneration and Nomination Committee consisting of 3 members, with 1 non executive and 2 independent ones, another one had a Remuneration and Nomination Committee consisting of 5 members, with 4 non executive ones. Another company had a Remuneration Committee formed of 4 members with 3 non executive, 1 independent member and independent Chairman, while another two companies that have established a Remuneration Committee, were both characterized by a number of 3 members with 2 non executive ones.

#### 4. Conclusions and Recommendations

By far our motivation when we started our demarche was to increase the confidence of all stakeholders in the quality of financial reporting and to promote and encourage organizations to develop good corporate governance practices. Like we stated before, the literature emphasizes a variety of reasons to study these sensitive aspects. One of the major outcomes of the process of corporate governance is to increase the stakeholders` confidence in the company`s practices of financial reporting and governance, fact that lead us to analyzing the existence and characteristics of the support committees for our selected sample. Although we have focused on emerging economies and we expected weak transparency practices, it does not mean that these analyzed aspects are not important, moreover, their importance is increased in these markets and the role of corporate governance practices is even greater in emerging economies in more developed markets. Even though in the selected economies the Codes of Corporate Governance specifically points the existence and characteristics of the support committees, after conducting our analyze, we can state that most of the companies do not comply with these requirements, their non-complying decision varying from case to case. Our conclusion is that we can not discuss about good corporate governance practices. Even so, we can observe from our investigation that the trend in this regard is encouraging. Like future research, we thought at developing our study by comparing the emerging economies from European Union with those outside this area. It is an interesting area of investigation, as every country has different regulations.

# SOME CONSIDERATIONS REGARDING THE MANIFESTATION OF FISCAL FRAUD IN ROMANIA

**Dumitrescu Serju, Avram Marioara**

*University from Craiova-Faculty of Economics and Business Administration,  
Craiova, Romania*

*codser2001@yahoo.com*

*marioaraavram@yahoo.com*

**Abstract** *In our paper we shall try to present two mechanisms of fiscal fraud used by economical agents and also found in the control actions performed by the fiscal organs at different commercial societies from Romania. The presented mechanisms refer to the fiscal fraud resulted from fictitious acquisitions of goods and services done by Romanian firms which have as beneficiaries other commercial societies which are fiscally registered in Romania. Being empirically examined, the fiscal fraud will be presented through the use of some figures which will describe the detailed operations step by step. For the cases we have chosen to present we will describe the real circuit of goods and money according to the documents. We will also refer to the possibility of identifying the risk of fiscal fraud that results from the reports provided by the economic agents for different state institutions. We will also consider the information provide by the books of prime entry and bookkeeping, documents which have to be written by the commercial societies according to the Law accountancy nr. 82/199, with further modifications and completions. The mechanisms of fiscal fraud in use can be identical with the ones presented in this paper or they can be different as „new elements” can appear; these „new elements” depend on the type of activity performed, the modifications the legislative framework, the performers’ creativity or other external or internal factors which are not identified by the fiscal organs. By identifying the fiscal fraud mechanisms and the way in which they function, the fiscal organs will be given the opportunity to take the necessary measures so that the fiscal resources of the state consolidated budget should not be affected by such operations. It is will known that we can speak of fiscal fraud and shadow economy in any country but ,according to the reports and statistics published by different international institutions, Romania’s shadow economy represent almost 30% from the Gross Domestic Product. The Romanian authorities should carefully think about this phenomenon as it requires strict measures to reduced it.*

**Keywords:** *fiscal fraud, mechanisms, control, fiscal organs, fiscal resources*

## **Introduction**

The tax payers creativity „to diminish” the fiscal obligations which have to paid to the consolidated state budget is beyond imagination as the tax payer considers his personal interest over the general one. The diminution of the fiscal obligations in Romania can be regarded from two perspectives: one subjective and the other more objective. *The subjective component* implies that the person who chooses not to pay the fiscal obligations analyses the risks he is exposed to. If he considers that the result has a minimum level of risk he decides to avoid paying the taxes. According

to *the objective perspective* the present society offers just a few personal examples out of which a fiscal honest behavior is appreciated so that the tax payer could perceive the social benefits returned by the state as a result of his contribution. The avoidance of paying taxes is a consequence of the fact that up to the present moment there haven't been taken measures to correlate the income of a given person with his/her actual expenses in a given period of time although the Governmental Prescript nr.117(2010), was adopted in December 2010. According to this document: "any income identified by the fiscal organs, under the conditions of the Code of fiscal procedure, income with an unidentified source requires a 16 % quota applied to the adjusted taxable basis according to the indirect procedures and measures of reconstructing incomes or expenses".

### ***The fiscal fraud regarding the source of goods or their fictitious consumption***

In his mission letter addressed at Bruxelles by the Chairman of the European Commission, José Manuel Barroso (2009), refers to the efficient European and international fight against fiscal fraud in the mandate of the designated commissioner (Algirdas Šemeta) for taxation, customs union, audit and anti-fraud in the period 2010-2014. According to the action plan for an efficient fight against tax evasion and fiscal fraud presented at Bruxelles commissioner Algirdas Šemeta (2012) stated that: „approximately one thousand billion Euro are annually lost in EU because of the tax evasion and fiscal fraud. This sum of money is not just an outrageous lost of useful income, but also a threat to fair taxation. Among the measures recommended in the action plan there is one that mentions that all the member states should be encouraged to adopt a basic rule according to which: „they could ignore any artificial agreement set in order to undergo the fiscal fraud and establish taxes on the basis of the actual economic activity.”

The British lawyer, Templeman (2001), stated: "A tax avoidance scheme includes one or more interlinked steps which have no commercial purpose except for the avoidance of tax otherwise payable, and can conveniently be described as artificial steps. A tax avoidance scheme does not leave the taxpayer any better or worse off but leaves the Revenue worse off". According to the information provided in the European Parliament by the tax researcher Murfy (2012), Romania annually loses over 10 billion Euro from the manifestation of the shadow economy.

Starting from here we shall present in detail two mechanisms of fiscal fraud by which the participants simulate operations of acquisition and trading goods and services, the only real purpose being that of avoiding the payment of the fiscal obligations and the desire to create a certain pretended legality for the operations mentioned in the documents.

The two mechanisms of fiscal fraud are based on real cases which have been analysed by one of the authors during his everyday activity as a Financial Guard commissioner. Such cases are often found in the activity fields of different commercial societies: trade, production, domestic services and constructions.

The main purpose of this paper is „to sensitize” all the decisional factors with responsibilities in the economical field since all the sums of money resulted from such operations are huge according to the information held by the Public Finance Ministry. According to the research performed by the authors, there have been identified cases when thousands of commercial societies declared, through 394 form, acquisitions of goods and services whose value worth millions Euro. Such

acquisitions are made from only one supplier even though he is not aware of them and he has not declared deliveries to those clients. The only purpose of declaring these as acquisitions is to create a source to the suppliers. In many cases „the final beneficiary” is the state and consequently the value of different works is increased without a real support and the state budget is prejudiced.

The presented fiscal fraud schemes are widely spread on the Romanian territory; these schemes are made of different links which are presented in detail in Figure nr. 1 „Fiscal fraud when the beneficiary fictitiously introduces in usage different goods to obtain some fiscal advantage” and in Figure nr. 2 „Fiscal fraud when the beneficiary has different goods for which he doesn't have legal documents”

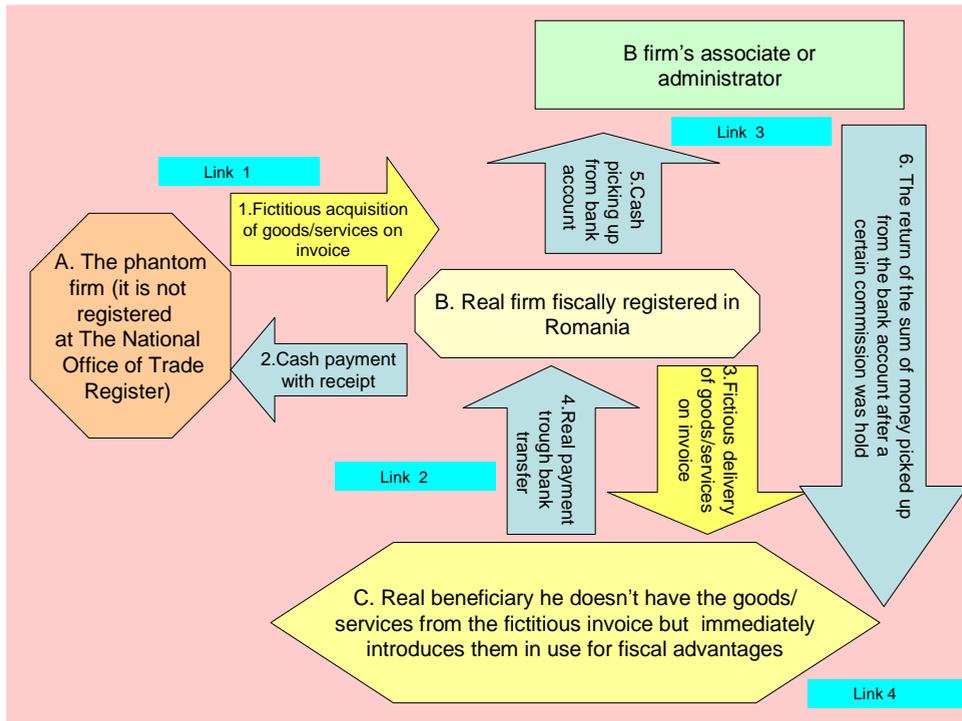

Figure nr. 1 „Fiscal fraud when the beneficiary fictitiously introduces in usage different goods to obtain some fiscal advantage”

Source: the author

*Link 1 – fictitious acquisition of goods and services and unreal payment using a receipt*

- the firms fiscally registered in Romania realizes fictitious acquisitions of goods and services based on invoices from phantom firms which don't function at the declared address, may be erased from the evidence N.O.T.R. or the firm's administrators can't be reached;
- the cash payment of the suppliers is done by using a receipt, exceeding the limit of payment imposed for juridical persons by the Governmental Order

nr.15/1996, with modifications; in this case the establish limit is of 5.000 lei/juridical person/day

*Link 2- unreal delivery of goods and services by using false invoice and real payment through bank transfer*

- the goods and services fictitiously acquired are now traded using fictitious invoices from firms which are registered in Romania and effectively function at the social centre or the fiscal residence.

The two fraud mechanisms can be differentiated according to the purpose and implications they create at the beneficiary of goods and services:

-in the first case, presented in the Figure nr.1 „Fiscal fraud when the beneficiary fictitiously introduces in usage different goods to obtain some fiscal advantage”, the goods and services are neither delivered by the supplier, nor do they exist at the beneficiary the whole operation having as the main purpose the diminution of the fiscal obligations as well as the removal of sums of money from the beneficiary’s firm.

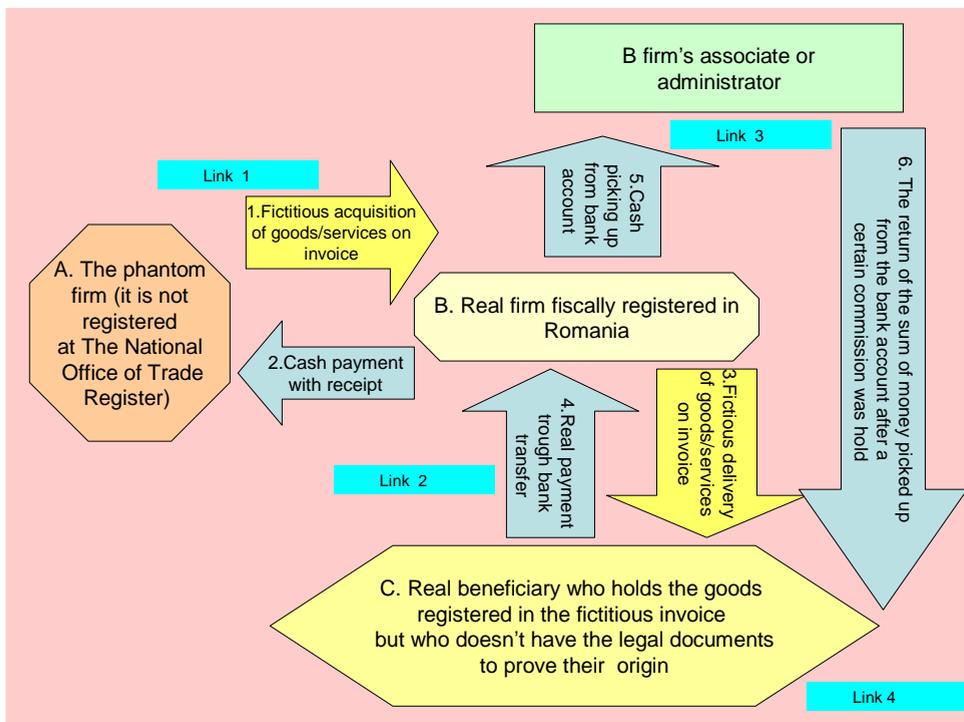

Figure 2 „Fiscal fraud when the beneficiary has different goods for which he doesn't have legal documents”

Source: the author

- in the second case presented in Figure nr. 2 „Fiscal fraud when the beneficiary has different goods for which he doesn't have legal documents”, the

goods and services are not delivered by the supplier but the beneficiary needs some legal documents to prove their origin. When it comes to services, these have been performed for the beneficiary by a different supplier who is not mentioned in the documents so that the final beneficiary has documents from another supplier who has not really performed the services. The fundamental difference between the two mechanisms resides in the fact that in the second case, for a certain good that really exists, the beneficiary gets a document to prove its origin and this document „demonstrates” his property right.

- the payments to the supplier firms which have provided fictitious invoices are done by the beneficiary firms „of the documents” through bank transfer; these payments try to provide a veil of legality to the operations

*Link 3 – the effective cash withdrawal from the bank account by the administrator or associate of B firm; the sum of money which is withdrawn is equivalent to the invoice value minus the bank’s commission;*

- in order to withdraw the sums of money resulted from operations that have not been really performed and to enable the beneficiary firm of the documents to take back the money paid for „documents”, the bank is informed by the firm who provides the fictitious invoices that the sums of money are withdrawn to perform operations with natural persons; the sums of money are needed for „the acquisition of scrap”, „copper” or even „salaries”; these operations are not under strict limit imposed by GO 15/1996, being considered exceptions (according to the given GO, a firm can withdraw up to 10.000 lei/day cash from the bank account).

*Link 4 – B firm’s administrator returns in cash the value of the invoice after he has held a commission; the cash is paid to the C firm’s administrator*

- later „the documents’ beneficiary” retrieves in cash the sums of money paid through bank account to the “supplier” after he has paid a commission between 2 and 10% from the operations’ value. These operations also result from the account extracts of B firm out of which we can observe that between the moment of cash collection through bank transfer to B firm from C firm and the moment of cash withdrawal by the B firm’s administrator there is a short period of time reduced to several minutes.

The fiscal implications of such operations consist in:

- the diminution of the obligations for VAT payment at the beneficiary firm;
- the diminution of the obligation for paying the profit tax at the beneficiary society;
- the attempt to confer a veil of legality for the withdrawal of different sums of money from the beneficiary firm by an associate or administrator.

The fictitious character of the operations also results from the fact that:

- the firms which provide „documents” don’t possess any means of transport, inventory objects or any other fixed means;
- they haven’t got any employees;
- for the reporting periods, the mentioned firms register losses in order not to pay a profit tax, so from economic point of view owning such a firm is not profitable;
- the firms are registered as VAT payers but in fact they don’t do that and moreover ,at the end of the reporting period, the state has to give them the VAT back;

- the associates introduce big sums of money in the firms but they can't prove the money's origin.

The identification of the fraud risk results from the information provided by the reporting documents declared by B firm. According to this information we observe that:

- the declared fiscal vector mentions just two obligations: the profit tax and VAT, that leads us to the conclusion that the investigated economic agent doesn't have any employees;

- the economic agent has not declared any working points at the National Office of Trade Register;

- in the annual balance sheet or semestrial reports we can't find any fixed means or, when they are mentioned, their value is insignificant as compared to the volume of activity performed by that firm

- the firm registers huge turnover according to the declarations on profit tax (101 form), without registering any profit or sometimes, when it appears, the profit is very small;

- the firm registers successive VAT deductions (300 form) for the acquisitions of goods and services, which are bigger than the deliveries of goods and services, so that at the end of the fiscal reporting periods the firm has VAT to reclaim from the state budget;

- in the legal papers they fill in, these firms do not put a tick for the option „require VAT return”, even though they would have the legal right to do so but this will consequently prove that their operations are illegal in the case of a fiscal control;

- from the informative declarations regarding the acquisitions and deliveries on the Romanian territory (form 394) made by B firm we identify major discrepancies between the acquisitions reported by B as being done from A firm.

The fiscal fraud also results from the information provided by the accountant evidence of B firm:

- in the accountant evidence we cannot find accounts from the following groups: 20 „Intangible assets”, 21 „Tangible assets”, 23 „On the process assets”, 26 „Financial assets” and group 28 „Depreciations of assets”;

- the value registered in „Total of the -in-the-red and in-the-black sums” for the accounts 37 „Merchandise” are very high; this proves that there is a certain „movement of merchandise stocks” in the sense that there are performed different successive operations for merchandise acquisitions and trading; sometimes at the end of the month there seems to appear a registration of high balance for the merchandise accounts; this demonstrates that the merchandise should be deposited in a warehouse. In order to avoid the registration of a high balance at the end of the month in the account 371 „Merchandise” (which implies the existence of a place where the merchandise is stocked and the presence of the person responsible for this) the firm uses the account in group 35 „Stocks held by others”, out of which we understand that the investigated economic agent doesn't possess the stocks and they are in the custody of another person.

- the values registered in „Total for in-the-black sums” at group 40 „Suppliers and assimilated accounts” and also in „Total for in-the-red sums” at group

41 „Clients and assimilated accounts” are very high; this can be interpreted as great sums of money which have to be paid to the suppliers and received from clients

- we don't identify any sums in the account 441 “Profit tax” or if the sums appear they are very small;

- in the VAT accounts 4426 „Deductible VAT” and 4427 „Collected VAT” big sums of money are registred, even though at the end of the month the account 4424 „VAT to get” shows an in-the-red balance; this proves that the economical agent has a claim from the state budget with the some value;

- the value registered in „Total for in-the-black sums” at gropup 45 „Group and share associates”, account 455 „Sums owed to associates” and group 46 „Debtors and different creditors”, account 462 „Different creditors” are very high because these values try to offer a plausible explanation for the great sums of money brough by the associates or creditors in the firm

- the value registered in „Total for in-the-red and in-the-black sums” at group 53 „Cash” are very high; in this case the debit shows represent the money brought by the associates and creditors while the credit shows the way in which the sums are used for the cash payment of fictitious acquisitions operations;

- the value registered in „Total for in-the-red and in-the-black sums” at group 60 „Stock expences”, group 61 „Expences for works and services performed by other persons”, group 62 „Expences for other services performed by other persons”, group 65 „Other exploitations expenses” are very big;

- there aren't registered sums of money in the accounts from group 42 “Assimilated personnel and accounts” or in the group 64 “Personnel expenses”

- the value registered in „Total sums” at the income accounts from group 70 „Net turnover” and 75 „Other exploitation income” are very big;

- balance of the account of 121 „Profit or loss” is in-the-red or in some cases is in-the-black with the small value reported to the sums of money registered in the income accounts; this demonstrates us that in the given fiscal year the economic agent has registered losses when the balance is in-the-red or profit when balance is in-the-black;

- balance of the account of 117 „Carried forward result” is in-the-red, i.e. the losses caried forward from the previous years; these losses are to be recovered from the next years' profits

## **Conclusions:**

As a general conclusion of this paper we consider that in order to discover and get more informed on fiscal fraud it is crucial to understand first of all the fraud risk to which an economic agent is exposed to. These risks depend on certain characteristics such as: the activity performed, the types of fiscal obligations he has, the flows of the legislative framework which supervise its activity, the ethic profile of the administrator or associate. *The type of activity* performed by the economic agent who is under investigation could be correlated with the average profit rates obtained by other firms which performe the same type of activity or a similar one. If the economical agent obtains profit rates under the average one or even more if he registers losses along several years this must be an alarm signal for starting a fiscal control to that particular economical agent. *The fiscal obligations* declared through the fiscal vector should be correlated with the declarations ofered by the economical agent under investigation. The sums of money registered in the declarations and the reports presented at different state institutions should also be correlated with the

volume of activity and the human and technical capital needed to perform the activity. *The legislative framework and its modifications* also have an important impact on the fraud risk because when the fiscal obligations increase this consequently determines an increase of the fraud risk. We consider that if we want to get a clear picture of the *ethical profile of the administrator or associate* we should consider the sums of money brought by these persons in the firm (through bank account or cash) whether they are considered contribution to the social capital, loan for the firm or other loans. What is more important is to correlate the above sums of money with their source according to the income declarations reported to the fiscal organs. We mention that according to the the latest legislative changes The Code of Fiscal Procedure (2013) stipulates that a natural person who is under investigation for income tax has the obligation to make a statement to the fiscal organ with reference to his possessions and incomes. We mention that the possessions and incomes which have to be declared by the investigated person are to be detailed in a new document which is to be released by the Public Finance Ministry in the coming months.

## INNOVATION IN THE CREATIVE INDUSTRIES – CASE STUDY OF AN EVENT PLANNING COMPANY

**Filculescu Adina, Cantaragiu Ramona**

UNESCO Department for Business Administration, Faculty of Business Administration, The Bucharest University of Economic Studies, Bucharest, Romania  
adinafilculescu@gmail.com  
ramona\_cantaragiu@yahoo.com

**Abstract:** *Creative industries have recently gained attention from economists and policy makers as they are said to contribute in a significant way to the economic and technological development of knowledge societies. In Romania there has not been too much talk about the way in which these industries are inserted in the larger chain of industrial innovation, nor about the particularities of their innovation processes which could provide interesting insights for the more traditional industries that are in need of a creativity boost. This paper seeks to fill this gap by offering a process view of business innovation in an event management company, which we argue has many of the characteristics encountered in organizations belonging to creative industries. Through an in-depth case study based on diary entries and interviews we uncover the way in which innovation is understood in this service sector and how this understanding is translated into repeatable business processes. Based on the review of the literature concerned with innovativeness in creative industries we have decided upon four important research themes: people, products, places and policies. By people we refer, first of all, to the entrepreneur who was asked to reflexively answer questions related to passions/interests, formal and non-formal knowledge and social capital in order to assess her entrepreneurial capacity for innovation. Also included in this category are the clients and the employees, which represent major players in the innovation process during different stages. Places are important because they are used in the definition of innovation: something new to someone somewhere, and also because they are regarded as a source of inspiration and a possible hindrance in the implementation of the desired event design. Products encompass the raw materials that are used in creating the flower arrangements and the general room décor as well as the technologies that stand behind them, while policies refer to national or local governmental mechanisms that seek to guide and fund innovation. These categories represent (f)actors that bring important contributions to the innovation process, while at the same time representing sources of major business risks for the event management company. The article follows the way in which these four items interact during the innovation process which was split into four stages: idea generation, negotiation of the idea, preparations for implementation and implementation of the idea. We conclude with the observation that innovation in event planning is human centered, the main referential system being based on the dyad company-client, a thing which has not been explicitly researched until now. Also we suggest that before trying to understand the way in which companies innovate, it is critical to undergo a thorough assessment of the entrepreneurs' perception of business risks.*

**Keywords:** *innovation; floral design; creative industries; small and medium enterprise; risk; entrepreneurship.*

**JEL classification:** M19; O31.

## **1. Innovation and Event Planning in the Framework of Creative Industries**

Creative industries are defined based on two criteria: creativity as an input and content or intellectual property as the output (Galloway and Dunlop, 2007). Nowhere in the literature regarding creative industries have we been able to find explicit references to event planning companies, and in this paper we argue that this service sector should be taken into consideration when analyzing creative industries. We also contend that studies of innovativeness in this sector benefit from the scientific findings published in the researches referring to innovation in creative industries.

Events are like theatre shows in the fact that there is only one chance to make everything right and then the experience is over and it won't be recreated in the same way ever again. These fleeting but powerful experiences are what event planners sell. Planning an event such as a wedding, baptism, funeral or a corporate Christmas party involves a blend of traditions and innovation that has to perfectly fit the requirements of the clients. Considered a standard of creativity because what she creates is the materialization of an idea or a dream, the designer is trying to make beautiful and useful objects, transmitting aesthetic emotions.

There are four prominent themes that are featured in the literature regarding innovation in creative industries: people, places, products and policies, and we will briefly present the main findings of previous research during this section to pick the categories then as research areas.

The locus of innovation in creative industries is both very close to the market and distributed inside a network of actors that contribute to the final product or service. Companies in creative industries have at their disposal multiple avenues for allowing clients to participate in the innovation process: (a) opening up the company's boundaries, (b) opening the product/service for co-creation, and (c) organizing identity convergence around products or services (Parmentier and Mangematin, 2012). Besides clients, companies in creative industries also work with project-based networks built on informal patterns of interaction which tend to repeat themselves in a series of projects and create semi-permanent ties (Daskalaki, 2010). These networks of collaborators are also quite mobile and fluid, reflecting the patterns of organizational learning as well as the socio-cultural developments in the industry (Daskalaki and Blair, 2003).

Place bears a significant importance in the study of creativity in these industries, as authors talk about clusters of creative enterprises (Lazzeretti, Boix and Capone, 2008) which make for vibrant creative cities (Hubbard, 2006; Hall, 2000) or rural settlements (McGranahan and Wojan, 2007). The point that these researchers make is that the sheer diversity of artists and innovators grouped around specific geographical locations enhances the creative potential of the entire region as members of this creative class (Florida, 2002) feed off each other's energy (Karenjit, 2012). Previous papers have also emphasized that locality can be conceived as a valuable source of innovation in terms of it offering visual raw materials and stimuli and a brand based on reputation and tradition (Drake, 2003). These trends of locally embedded economic relations appear not be threatened by the new advances in ITC; on the contrary, industries seem to be more inclined towards clustering than ever before (Karenjit, 2012).

In terms of policy, the main concern is to understand the nature of the creative sector (definition, boundaries, categories etc.), then to gauge the dynamics of growth of the creative industries, the links between the level of innovation in the creative industries and the traditional industries and to find ways to grow the creative industries as they seem to be important contributors to a nation's economic growth (Muller, Rammer and Thruby, 2008). As Cunningham (2011) says, creative industries represent a part of the service sector with a "crucial input into manufacturing on the supply side and a central role in shaping consumption trends and choices, [that] remains on the margin of innovation policy, planning and research" (p. 241).

## **2. Research Methodology**

This article presents the findings of an exploratory research based on an in-depth case study of a single Romanian SME active in the event management industry. We take a close look at the way in which innovation is enacted as a process which combines people, products, places and public policies. By people we understand the business owner, the employees and also the customers. Regarding the business owner our research questions were modeled based on the framework provided by Sarasvathy (2001): (a) who she is – her qualities, her passions, her dreams; (b) what she knows – her formal and non-formal education; and (c) who she knows – friends, family, customers, other business owners, etc. In terms of the employees, collaborators and clients, our research questions sought to find out the stages during which they become prominent actors and to map their inputs into the innovation process as well as the business risks involved in the implementation of new ideas for which they are responsible.

Places are important from several angles: first of all, innovation is place-contingent (i.e. we call innovation something that is new to a certain place); second of all, in this particular service sector, places serve as major sources of inspiration, but also as major hindrances for the implementation of new ideas.

Products are the results of the creative process, but they are also sources of inspiration, e.g. adapting natural or man-made objects from other domains to the event design. Here we also discuss the influence of technology on the available means to realize a certain vision: creative approaches in conceiving, developing, producing, using and recycling materials are important sources of innovation (EC, 2012), as well as new plant design and new techniques for maintain the freshness of the flowers and enhancing their features. Finally, policies provide support for innovative endeavors, while also providing guidance and hinting at what the future trends will be.

The aim of the article is two-fold: (a) understanding how entrepreneurs from the creative service sector view innovation and (b) how this translates into business processes. We collected information through in-depth interviews and also diary entries, as one of the authors is also the business owner.

## **3. Enrose - Company History**

The company under study is called S.C. Enrose Design S.R.L. (hereafter Enrose) and it was registered at the Bucharest Register of Trade in January 2012 as a new legal entity, although it had begun its activity in 2006 under another legal name. Enrose is run as a limited liability company whose sole proprietor is a young entrepreneur with a consistent background in Business Administration developed during a master program in Business Administration at the Bucharest University of

Economic Studies, a master in Entrepreneurship in collaboration with Anglia Ruskin University of Cambridge and, currently enhanced with a PhD research regarding women entrepreneurship in innovative services.

Enrose started as a workshop which offered high-quality dried flower arrangements in innovative shapes and containers as gifts or as decorations for different events. After a couple of years, spotting the opportunity on the market, the company expanded its portfolio to fresh-cut flower arrangements. Over the years, the entrepreneur noticed a distinct lack of good flower shops in Bucharest. After working in the floral domain and feeling that the demand was not satisfied, she saw the opportunity of opening a company with a new concept. This job offers her the possibility to earn a high-salary and also pursue her life-time passion for design and beauty, which suggests that this venture is a mosaic of life-style, salary-substitute and genuine entrepreneurship.

The expansion from flower arrangements to whole-event design came about naturally at the request of the clients because, as she argues, people usually prefer to buy everything from a single source and not waste time with multiple meetings and negotiations with different suppliers. The entrepreneur decided that the company had the necessary capabilities to pursue this market opportunity, especially due to their history and her recent organizing skills acquired after a one year course in Project Management. At the moment, they offer consultancy services for a large pallet of events like: themed parties, anniversaries, weddings, baptism parties, Christmas parties, corporate parties, concerts, product launching events (marketing events), trainings, conferences, fairs, trips, etc. from creating the concept until its implementation.

As regards their clients' profile, Enrose works with individuals to provide floral arrangements for holidays, birthdays, special events like weddings and graduations, etc. In addition, they look for long-term contracts with business buildings, hotels, restaurants and other businesses that need flowers delivered or arranged on a regular basis and which organize corporate events. These clients provide a more stable and consistent income flow and they also present an easy way to highlight the company's designs to other prospective flower-buyers.

#### **4. The Entrepreneur as an Innovator**

First of all, the entrepreneur sees herself as an avid networker, taking pride in her acquired interpersonal skills and abilities to form relationships and to facilitate the transfer of knowledge to improve coordination and control (in relationship with employees, suppliers, customers, potential customers). As in most creative businesses, a healthy network is deemed vital for the entrepreneurial success which is mostly built on valuable relationships and visibility. Another important skill that is useful when dealing with people is the ability to accept and embrace uncertainty and to take actions based on insufficient, unreliable or conflicting information. The entrepreneur also envisions herself as a flexible person who quickly adapts to changes and prefers to mold on the circumstances rather than try to control the unpredictable environment. These two characteristics, coupled with others such as self-confidence, responsibility, determination, integrity, curiosity, intuition, patience, and a sense of humor bring added value to her work and differentiate her from her peers in the industry, while also becoming imprinted on the company's organizational culture.

Besides these psychological characteristics, the entrepreneur is also involved in multiple activities for self-development such as teaching an “Entrepreneurial Culture” seminar for the freshmen students at The Bucharest University of Economic Studies, Faculty of Business Administration, which facilitates a constant exchange of ideas with young students. She is also a member of the Women Business Club which organizes monthly meetings and also publishes a magazine for business women and she is also asked to join conferences and talk in her quality of a young female entrepreneur to students and other entrepreneurs.

With a work ethic that would politely be described as “tireless”, she works endless hours to make sure every event is perfect in order to meet her client’s expectations and hers as well - she is often the hardest to please. One might think that after so many events, she is not so enthusiastic about the next one, but when you meet her, you immediately understand it is much more than a job for her. With a denomination like “Enthusiast entrepreneur, floral design lover, making events happen” one can see that there is a true passion underneath it all that keeps her restless until she sees the big event come to life. And passion always does the work. When she walks into a room, she does not see only the flower arrangements; she sees the layout, the flow, the linens, the signage, and all the other details that go into each and every flawless event. With an eye for detail, a commitment to her craft and a passion for bringing unique ideas to life, her mission at the end of the day is to orchestrate an unforgettable event that her clients will happily remember.

Besides this, an entire team of professionals is needed to work out each event. Designers and handymen work tirelessly, at all hours, to make sure everything fits into place. There are many hard workers on the team, many of whom the clients will likely never meet, that are 100% essential to the success.

## **5. Enrose’s Definition of Innovation**

Innovation has always been related to the introduction of something new to a certain field, and the underlying newness has to be established in comparison with a certain referential system. For example, artistic innovation is defined in comparison to a referent which can be either: (a) all the other organizations in the field on a global span, (b) all the other local organizations, or (c) the history of the organization under study (Castañer and Campos, 2002). The choice of referential system should be coordinated with the purpose of the innovation study. If the global innovativeness of an organization is under scrutiny, then the cosmopolitan referent is the most useful, but if we want to assess the growing level of innovative change in an organization, it might be more useful to compare the level of newness of today with the historical past of the same organization.

In this article we are concerned with innovativeness as it is defined by managers of event design businesses and the results of the case study indicate that the most useful referential system is the one in which the two axes measure the newness of the design for the company and for the client. Paraphrasing Csikszentmihalyi (1990) we could say that “[innovation] is not an attribute of individuals but of social systems making judgments about these individuals” (p. 198) and, in this particular industry, the most important social system is the client base. Consequently, borrowing the terminology from the creative industries literature, we can state that most of the innovations described by the manager of Enrose have a hidden nature due to the fact that they represent tacit agreements between the manager and the clients based on a thorough knowledge of people’s tastes and current fashion trends, they involve

the users' preferences in the design process and some of the production solutions are one-time innovations that might not necessarily be picked up by the company or are non-transferable to other situations (Miles and Green, 2008).

The fact that the main referential system is based on the dyad company-client is reinforced by the fact that the entrepreneur sees innovation as "a new method of doing things that has a positive impact on the quality of the client's life. The purpose of innovation in event organizing is to transform moments from the lives of normal people in larger than life experiences... To be innovative is to engage in continuous improvement of your client's lives." This interview extract gives innovation a very humane orientation, a trend which is also encountered in other industries where design is said to be dictated by users' needs and preferences (Giacomin, 2012).

In terms of comparisons of innovativeness among companies from the same industry, the main factor of concern appears to be the level of investments in logistics or event-production facilities such as high-end and fashionable furniture and fittings, table clothes and tableware etc. which are seen as indicators of the degree of coordination with leading global trends, thus innovativeness. This type of innovation is clearly expressed in the company's financial documents and it is easily observable by external parties. Therefore, we can talk of the double-sided innovation that is based, on the one hand, on large financial endowments for a trendy inventory and, on the other hand, on the creativity enacted in the process of satisfying each client's requests.

## **6. The Creative Innovation Process**

### **6.1. The generation of an idea**

'Event design' is not a pretentious phrase; it stands for the harmonious result of the meticulous thinking of the designer who sought to incorporate the client's needs into a unitary vision. The world of floral design offers stunning scenery and countless rich sources of inspiration. All successful entrepreneurs in this field share a passion for flowers and a free creative spirit, but these are often not enough. Best floral designers also have a sound knowledge base, and a desire for training and continuing professional development, which sets them apart from amateurs and beginners. The end result is to promote knowledge that will lead to the creation of floral designs and to the preparation of a floral and event design business characterized by ethics, professionalism and total commitment to the clients' dreams.

The process of idea generation is based on a mixture of different sources of innovation. First, there is the person of the entrepreneur who continuously seeks knowledge. Reading books, taking leadership, negotiation techniques and public speaking trainings and participating at business conferences and artistic events are just some of the means through which she enhances her creativity. Secondly, the entrepreneur invests most of the company's profits in acquisitions of up-to-date equipment and technologies which are in accordance with recent trends in decorations. Thirdly, in order to become a pioneer in the event design, she collaborates with experts in the field and in connected fields (architecture, construction, arts and music, marketing agencies). Participation at conferences and workshops held by experts in event management enhances the entrepreneur's capacity for innovation, and these events constitute an important networking opportunity.

Working closely with the clients is one of the major sources of inspiration for new ideas, but this involves also certain kinds of risks. Although clients that are highly motivated but with a limited knowledge of technological possibilities are more prone to introducing radical ideas than the company's designer (Kristensson and Magnusson, 2005), that same lack of knowledge might induce a stretch beyond the company's production capabilities and the manager then runs the risk of either disappointing the client during the negotiation stage or after the implementation stage. Face-to-face communication may be particularly important for the transfer of knowledge; everything is best explained and demonstrated in person. Finding ways to meet customer desires in an attractive manner and taking care of the budget in a timely manner is always a challenge for the event manager.

Another constraint that leads to innovation is the nature and space and this is because an event has to be perfectly fitted in the scenery or a specific event hall. Most of the times, the event design needs to be adapted to fit these natural or man-made shapes in order to be appealing to the beneficiary.

## **6.2. Negotiation of the idea**

In selling ideas and concepts to her customers she makes use of the following techniques: presenting the features with an emphasize on the benefits, showing flexibility to the budget they want to invest in their event, making visual boards and sketches or even live demos for a better understanding of the final outcome. For example, if she wants to recommend a live band for an event, then she could invite the client to one of the band's performances in a different venue to really feel the atmosphere. Or she might do a demonstration for the wedding bouquet or for the table center piece to have a clear representation of the color scheme, textures and materials to be used. These methods also diminish the resistance to the initial proposals. The entrepreneur is often met with resistance to new trends, techniques and technologies coming from customers and until they adopt the new ideas it takes time and patience.

Another important aspect is the negation that leads to a final agreement and the signing of a contract. In this particular phase, there is a risk that other decision makers appear and impact the progression of the project and this is where she makes use of her adaptability skills. For example, she might discuss with the bride all these aspects, but the decision power might be held by the groom. Or perhaps the godparents have a decisive say in the end, and she needs to detect these threat early on and concentrate on convincing the person that will have the final say.

## **6.3. Preparations for implementation**

This and the last stage are the periods during which multiple on-the-spot solutions are given to "everyday problems" which shows that innovation has a planned dimension and a spontaneous one. The spontaneity of the innovation is visible only from the position of a practitioner: in this case, the workers and the managers. During this stage the network of professional gets activated and every task is allocated to an individual or a company, while the manager acts as the conductor of the orchestra. Most problems arise from lack of coordination between parties or misunderstandings in knowledge transfer. This stage can be very long and it represents the time when the entrepreneur sets things in motion and starts investing time and money into the actual event plan. As most of the guidelines for the event have been set during the previous stages, now innovation can arise as a solution to

mundane or unforeseen problems, thus being required by the circumstances and by the desire to accomplish the set goals. This is the stage during which unforeseen events can ruin the whole process of careful planning, such as a relative interfering and offering another venue and a different event planner, a marriage proposal being canceled etc.

#### **6.4. Implementation of the idea**

This stage usually takes a couple of days, and it represents the most difficult task and the most challenging part of a project. It requires flexibility, coordination, team work, time management, and physical endurance. For the entrepreneur it is of outmost importance to register the clients' feedback and she makes use of post-event phone calls or other means of contacting the clients to get their input. For the learning stage in the innovation process, implementation is highly important because it provides customer validation for certain initiatives and the feedback necessary for the entrepreneur to know which aspect should become company policies and which should be dropped.

#### **7. Conclusions and Future Research**

One of the main findings is related to the referential system that is in use in the event industries which is based on the dyad client-company. This is something unusual because most of the literature on business innovation compares the companies from the same industry and does not take such a relational approach. The innovation paradigm that we propose puts emphasis on a number of research questions: Is innovation threatened by copying or is it protected by its hidden nature?; b) Is this sector of the economy innovating at a different pace than the manufacturing sector?; and c) Is there a need to uncover the innovation process in this sector so as to provide insights for manufacturers looking to achieve artistry in mass customization?.

Next, we uncovered the fact that innovation is a process that is concomitant with risk assessment and risk mitigation and that a greater understanding of the innovation process has to start from a thorough research on the perceived business risks and the ways in which the introduction of something new modifies the risk-portrait of the company. Most important are the risks associated with the fact that most creative companies provide 'experience goods' which the client can't try before acquisition and whom bring clients a degree of satisfaction that is utterly subjective and intangible. Therefore, the study of the risks involved in innovation may turn out to be the perfect recipe for unraveling the nature of the innovation process which is not as linear as it appears in retrospect (Green, 2008), but rather sinuous and continuously changed by internal and external factors which for the company can be regarded as risks.

In terms of policies, there is a clear lack of government support for innovation in this particular field of the creative industries and we propose two methods through which the system of R&D could help develop the quality of events in Romania: a) universities should be supported by national funding to create research centers in partnerships with event planning companies and b) introduce in their curricula aspects pertaining to innovation in the creative industries, especially in the case of business schools and liberal arts universities, but also technical universities.

Because it was a single case study analysis, the conclusion drawn in this study could be further enhanced by a more thorough research which would seek to discover if

the same definition of innovation applies to all the companies in the industry or there are multiple ways of seeing and enacting innovation inside the same industry. Also, there is a stringent need to research the role of female entrepreneurs in innovative domains, and this is going to be covered by one of the authors' PhD research thesis.

# DOES CIVIL SOCIETY CREATE SOCIAL ENTREPRENEURS?

**Gauca Oana, Hadad Shahrazad**

*UNESCO Department, Faculty of Business Administration, Bucharest Academy of Economic Studies, Bucharest, Romania*

*gaucaoana@yahoo.com*

*shahrazada1988@yahoo.com*

**Abstract:** *The purpose of this paper is to analyze whether civil society can enhance or stimulate on its own the creation of social entrepreneurs, by studying its traits and the various definitions attributed to it. The main question that the paper wants to answer to is <Does civil society create social entrepreneurs?> and the main approach used in this research paper is the theoretical one. By studying existing articles, research studies and books on the topic, the paper tries to emphasize the various dimensions that civil society can embrace, as pictured by various authors, as well as how these dimensions can relate to social entrepreneurs and the emergence of social businesses. The paper is not meant to be a breakthrough in the field, but rather to launch a question that is related to very important topics these days, social entrepreneurship, social innovation, social businesses and their connection to a very much debated topic-civil society. The paper is a work-in progress and wants to stimulate the research regarding the search of the sources of social entrepreneurship, in order to analyze them and better establish them as incubators for the future studies. It wants to be of use to whoever is researching the concepts illustrated above, as well as for people who want to get in touch with the new buzz words of the academic and entrepreneurial fields. The hereby paper stands, as previously stated, in a theoretical framework and the findings represent a mere analysis of the cause-effect relationship between the characteristics of the civil society and those of social entrepreneurs. However, we are of the opinion that it can be a very good starting point for the ones interested in the domain, to analyze more sources of social entrepreneurship or further refine the answer to the question addressed in this article.*

**Keywords:** *civil society, social entrepreneur, social change*

**JEL classification:** *L26*

## **1. The Relation Between Civil Society and Social Entrepreneurs**

When talking about the traits of the social entrepreneurs, we cannot stop on wondering what environments are best suitable for fostering these traits, for encouraging the real life person to act as an agent of change, to assume chances and focus his/her attention on the factors that cause a certain social problem and the way in which they can be hindered.

Although these environments can be various, we decided to focus on one specific concept, which has become of utmost importance within the last few years, namely Civil Society. We cannot help on asking if Civil Society, such an omnipresent and under constant development organism, which deals with the needs of the society, fosters or does not foster social entrepreneurs.

However, in order to thoroughly analyse whether Civil Society is an incubator for

social entrepreneurs and social change or whether it raises barriers against it, one must first understand what civil society is and how it acts.

We are not trying to make a case regarding civil society nor do we try to define it, as there are entire articles and research theses that do that. Our intent is to clarify the concept based on specialised literature and different points of view.

Petrova in her quest about the civil society in post-communist countries, makes a very good point regarding the status of the concept in the literature:

" *There is no consensus on what civil society is or what constitutes it (e.g., Hyden, Court and Mease, 2004). Scholarship drawing on various disciplines—political science, sociology, area studies, political philosophy—abounds with definitions and conceptualizations of civil society. They range from the "ether" of participatory citizenship intuitively associated with democracy, to general ideas of "democracy from below," to the "broad base of active citizens able to influence decisions that affect their lives" described by USAID writers, to the space or middle-level organization between the family and the state, independent of the state (e.g., Varshney, 2001; for a review of definitions)*" (Petrova, 2007: 1278)

No matter the disagreement, the concept of civil society has gained a lot of recognition during the last years and is allegedly one of the solutions to balance political governance.

The roots of civil society go as far back as the 18<sup>th</sup> century, when people tried to redefine their statute in the society and when social order was undergoing a visible decline.

During the following years and centuries, the concept was further refined and enriched, as Anheier (2004) emphasizes, with notions of *civility* (Elias, 1994), *popular participation and civic mindedness* (Verba et al., 1995), *the public sphere* (Habermas, 1992), *social capital* (Putnam, 2000; Coleman 1990) *culture* (Gramsci, 1971) and *community* (Etzioni, 1971).

This concept is a very powerful one in the USA, whereas it has started more recently to gain acknowledgement in Europe. One of the arguments that stands for its increasing power is the recent desire of the EU to include the civil society in the decision making process, regarding it as a powerful source to connect to the citizens of the European Union and of Europe as a whole.

CINEFOGO (Civil Society and New Forms of Governance in Europe) Network of Excellence, which was funded by the EU within the 6th Framework Programs focuses on the importance of improving citizens' participation in governance. This requires new knowledge on the importance of social and cultural diversity, active citizenship, civic participation and organized civil society, all issues that have become more pressing with the on-going enlargement of Europe—a Europe characterized by growing inequality in economic and social conditions of the citizens, including education, but also increased diversity in the perception of how to proceed in the process of economic, social and political integration of the European nation-states (CINEFOGO, 2012).

But we shall leave that aside, for the moment, as it is necessary to understand more of the concept. Helmut Anheier, in his book *Civil society: Measurement, Evaluation, Policy*, regards *civil society as the sphere of institutions, organizations and individuals located between family, the state and the market in which people associate voluntarily to advance common interests* (Anheier, 2004: 46 ). Though he does not pretend it to be a complete definition and he underlines the fact that it does not encompass all of its aspects, we consider it to be a very simple and clear one.

As such, we can underpin the three main characteristics of this organism, which shall or must be encompassed in any given definition:

- Structure: organizations, individuals and institutions;
- Process: voluntarily association/ networking;
- Objective: advocate common interests of the society.

The Civil Society is thus represented by all non-governmental institutions or networks that are a separate entity from the government and they act with the purpose of social wellbeing. It can be comprised of people, NGOs or even the business world.

When talking about so many units, each with its own dimension and specific characteristics, with a set of values and individual activities, it is obvious that the interaction among them and the activity of civil society affects these sets of values. Just like Tonkiss, Passey, Hems and Fenton observed in *Trust and Civil Society*, the latter may have a strong impact upon culture, religion, behaviour of individuals, the economy or the government.

This is an extremely important aspect which is at the grounds of our quest about civil society being an environment of development for the people it works with.

Michael Edwards (2009) as cited by Vaduva (2012) states in his 2009 book, *The Civil Society*, that “the civil society is much talked about but rarely understood(...) It is impossible to have a conversation about politics or public policy these days without mentioning the magic words *civil society*” (Vaduva, 2012:222). Is this true? Is civil society only a buzz word or is it “our last best hope?”(Rifkin, 1995: 106), as Rifkin says?

Some argue that while government institutions are poorly organized to tackle with complex problems, it is in the responsibility and in the power of the civil society to take the ideas to another scale (Murray, Caulier-Grice and Mulgan, 2010). The problem is whether the civil society has the resources, the capital and knowledge to do so. Is it powerful enough to handle these complex problems? More importantly, is it capable enough to gather the people necessary to do so or educate them, empower them to do so? We posit that even though quantitative measurements are not yet demonstrating this, there is evidence throughout the world that the answer to these questions is at least partially, yes.

In fact, civil society acts like a link between all the characteristics previously mentioned and has a very important role due to the fact that it builds a sense of community and is able to share resources and connect networks in order to achieve certain goals. A very nice phrase of Alexis de Tocqueville used in his book *Democracy in America*, when he referred to the ability of a nation to voluntarily solve their common social problems was “the art of association”. This completely underlines the key feature of the Civil Society, which is association in order to create value for a common purpose.

This brings us closer to how the civil society creates value. Though a difficult and very important aspect, we shall but merely analyse it, as it directs us to the answer of our question. Does civil society create social entrepreneurs?

One of the answers could be that civil society creates civic entrepreneurs. Well, this is rather wrong from one strong point of view, namely the fact that civic entrepreneurs are economic entrepreneurs, who deal with economic assets for economic purposes, with the distinction that they believe success can be achieved only through collaboration - they know how to work with people.

As Henton, Melville and Walesh (1997) see it, they are involved in their community

out of enlightened, long-term self-interest. They believe that their personal long-term interests and those of their organization are to some extent tied to the health of the local economy and community. They view it as being in their best interest to work towards a long-term positive interconnectedness between business vitality, schools and universities, physical infrastructure, natural environment, and tax base. (Henton, Melville and Walesh, 1997: 4)

On the other hand, social entrepreneurs act with a social purpose, with and for the interest of the community and of the social wellbeing, leaving aside economic benefits for self-interest.

In order to see if social entrepreneurs can be born from the environment that civil society creates, we have to start from the dimensions of the civil society concept. According to Anheier (2004), the dimensions to be measurable and assessed, in order to conclude what value can be created, are:

- Structural dimension: composition and sources of support of the civil society;
- Legal dimension: the regulatory environment in which it operates;
- Impact dimension: contributions of the civil society;
- Value dimension: norms and cultural elements.

The last two are the dimensions that are of an utmost importance in our analysis, as they emphasize the contribution that civil society has with his actions, the purpose of its actions and the added value it wants to bring.

We believe that by understanding this, we come to the functions of the civil society, which may be divided as follows:

- To create social capital;
- To find solutions to social problems through collaboration between various entities but by preserving a high degree of independence to the state;
- To engage motivated people voluntarily to act on common purpose;
- To raise capital from various sources in order to sustain itself.

By watching all these functions, it comes naturally to find the link between each and everyone one of them with the traits of the civil entrepreneur and of his/her actions. Let us start with the creation of social capital, another ambiguous term.

For the sake of simplicity, we shall consider that social capital is about the value of social networks, bonding similar people and bridging between diverse people, with norms of reciprocity (Dekker and Uslaner, 2001). Therefore, social capital is the power of networks, of people working together and sharing information.

The fact that civil society creates networks through collaboration of various units is easily understood. Which is almost as simple to depict is the fact that social entrepreneurs use networks in social ventures, in order to add more value to the sustainability of the innovative solution. A very good example is Grameen-Danone venture, started by Muhamad Yunus together with Danone, in order to offer enriched yogurt with 30% of the necessary vitamins to people in Bangladesh.

This venture was built on an existing infrastructure of social network, upon collaboration and information sharing.

Therefore, we want to underline the fact that the creation of network, lessens the activity or the possible future activity of a social entrepreneur, by offering a vast infrastructure of connections that a future social entrepreneur can and will use in his activity. Moreover, the future social entrepreneur will enrich the existing network by supplementing with other sources and creating thus, more social capital.

Further, the second characteristic is finding solutions to social problems which is

also nascent to social entrepreneurial activity. Why?

We posit that, by offering the process of defining and understanding a problem, analyzing the main possibilities in which it can be solved and finding the way of implementation empowers all the units involved in the process (including the possible future entrepreneurs) with the knowledge of problem identification and finding the solution.

Moreover, it empowers them with the confidence that if they see a problem and put an effort into finding a solution, the problem will be solved in the end. Thus, a powerful motivation is triggered, motivation that is the most important pillar of the entrepreneurial activity.

Furthermore, this process is an important one in the entire entrepreneurial activity and may constitute the difference between success and failure.

Thirdly, we come to the voluntarily engaging people to do something for the purpose of the social wellbeing, with a strong sense of community and with desire to perceive this as a common goal.

Willingness and motivation are strong characteristics of any kind of entrepreneurs, whether they are social, business or other types. Determination to involve yourself in a problem, to fight for it and to continue no matter the impediments and the problems you might face, these are the characteristics we want an environment to foster.

Humans usually need reasons, whether sentimental or ration, to selflessly engage in an initiative of civic nature.

Civil society does that, as it encourages people to take a stand for what they believe in, to roll up their sleeves and fight for it, to overcome the barriers of the government, of the gravity of the problems and of the lack of interest of others.

Therefore, in this regard, civil society is for sure, not only an environment that fosters social entrepreneurship, but it also gathers together people that have the opportunity to transform themselves in social entrepreneurs, encourages them to become agents of change.

Civil society seems to create a *Do It Yourself* rule...if you see a gap (a problem), fill it in. Find that one service/solution that offers the necessary items for the problem to be solved. Be yourself the one to act for a purpose you believe in!

It is important to take a note that this characteristic is rather unique from all other environments. On the issue of "participation" non-profits have a voluntary system whereas government has an automatic/coercive one and business a quasi-voluntary, based on economic needs.(Gidron, 2010: 405)

On the issue of "motivation" Anheier characterized business organizations as having material motivation, government as purposive and non-profits as solidary. (Gidron, 2010: 405)

Last but not least, we reach the final characteristic, that of raising capital for the sustainability of its actions. We perceive this to be, in an equal manner, a source for social entrepreneurship, as well as a barrier to it.

Sustainability of a social venture is one of the most important aspects, one deeply explained and emphasized by Muhamad Yunus in his book, *Social Business*. Without the aspect of economic sustainability, a social venture would become a charity.

Therefore, the source for fostering social entrepreneurship comes from providing its users with the infrastructure needed for finding the suitable funds of capital, the right philanthropists or government funding.

However, it also sustains a barrier - that of raising capital from other independent units-, which might hurt the independence of the social venture and is not for sure desirable.

More often we relate the growth of social entrepreneurship with existing trends in the market such as the growth of consumer awareness, sustainable business practices, the ridiculous economic gap between business leaders and the rest of humanity. Furthermore, democracy tends to be the most proper environment to foster social entrepreneurship; this means that even the political regime can be a barrier to this kinds of endeavours. So there are better chances of success if we are on the same barricade with the system, and not against it.

The limitation of the civil society concept as an aggregation of institutions, organizations and individuals specifically, is the lack of recognition *that the organizational reality of civil society requires more than individual trust and willingness to participate in various forms of action. Factors like funding, managerial experience, media coverage, and the like—or in general resources—do not figure in individual level accounts of civil society* (Petrova, 2007: 1282)

Therefore, this seems to be vicious circle, as Civil Society needs people with certain knowledge but also empowers them with multiple knowledge and know-how, in order to become, on their turn, agents for the society, entrepreneurs with the same common purpose, social wellbeing.

## **2. Conclusion**

We posit that, the analysis of the concept as well as of the objective of the civil society leads us to a favourable answer regarding the question addressed in the beginning of the paper.

The environment of the civil society is for sure an incubator for social entrepreneurs and social ventures. It offers infrastructure for social capital, teaches self-reliance and efficiency, advocates for sustainability and more importantly, militates for social wellbeing and self-implication in obtaining it.

We share the point of view of some scientists who are of the opinion that of crucial importance is the fact that universities have the moral obligation to produce not only innovative and entrepreneurial graduates (Kwong, Brooksbank, and Jones-Evans, 2006; Thompson, Kwong, and Jones-Evans, 2012), but also civically aware and socially responsible citizens (Steiner and Watson, 2006). The society in which we are living experiences a kaleidoscope of persistent problems which now are actually on the rise more than ever, and the ones who can alleviate them are the social entrepreneurs. Therefore, by means of this article we try to suggest the premises of our next article "Universities have the moral obligation to foster, enable and create social entrepreneurs" in which we argue for the duty of universities and society as a whole to support and promote social entrepreneurs, Besides, we argue in favour of the shift from the traditional businesses towards the social businesses which are more than an adequate solution for the current economic, political and social situation the world is facing. As a concluding remark, we adhere to the opinion of Alex Nicholls (2011) that social entrepreneurs represent a new generation of civil society actors who are driven to address the systemic problems facing the world today.

We look forward to reading other papers that would address this question as well as emphasize other sources for the creation of social entrepreneurs.

### 3. Acknowledgements

We wish to thank our coordinating teacher, PhD. Prof. Carmen Paunescu, for encouraging us to study this field, and also PhD. Prof. Sebastian Vaduva for sharing with us his personal insights related to the study of the civil society concept. We found both their guidance very valuable. Last, but not least, we would like to mention that this article harnesses partial results of our doctoral theses on Social innovation in higher education (Oana Găuca) and Corporate Social Entrepreneurship - The role of individual and organization characteristics in building Corporate Social Entrepreneurship (CSE). The case of multinationals (Shahrazad Hadad), Business Administration Doctoral School, Bucharest University of Economic Studies.

# THE AUTHENTICITY AND TRACEABILITY OF FOOD – CONSUMERS PROTECTION FORM

## **Pascu Emilia**

*Faculty of Touristic and Commercial Management, Christian University "Dimitrie Cantemir", Bucharest  
pascu.emilia@ucdc.ro*

**Abstract:** *The quality of food is closely related with food safety, highlighted by their authenticity and traceability. Essentially the food it is a carrier of information, his quality reflecting off the capability of the body to decode them and so to provide a healthy lifestyle. Each individual, as well as the community, is preoccupied by the great problems of food, eating and the food behaviour, seeking the right solutions to the questions: what, how, when, and where do we eat to satisfy our physiological necessities. Food and food behaviour are essential determinants of our numerous pathologies, appreciating that many of the severe diseases may be prevented by lifestyle changes where the food is playing a key role. For authentic products, in this article there are presented information regarding benefits of traceability of products. The traceability of food products can be obtained by registering the ups and downs of the physical flux obtained during the production process. The objective of traceability is to obtain total control on products by individual and group identification to intervene in case of post-processing defects or any inconvenience. In traceability the "one step back, one step ahead" principle is applied. This means that any company has the obligation to have all the necessary information regarding the product, including the nature of raw and auxiliary materials and to possess information regarding the date and delivery destination. For the accomplishment of this wish, the individual identification of the goods, products, locations and place is indispensable. The traceability of the product is based on the identification code. It is monitored the changes that have occurred during the production processes, transport, storage and distribution flux.*

**Keywords:** *Foods, consumer, safety, health, sustainable development*

**JEL classification:** *M10, Q01*

## **Food authenticity**

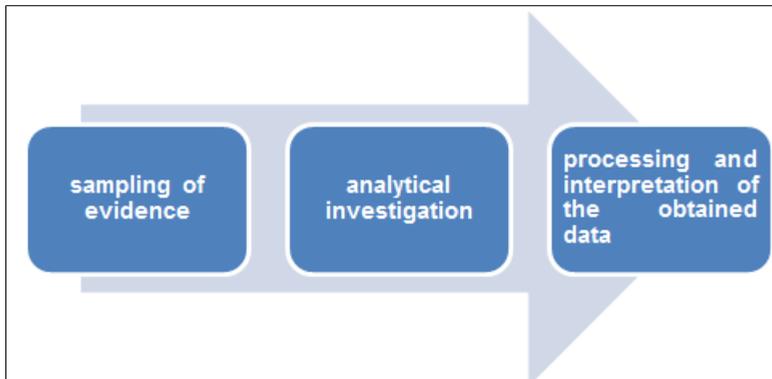

The authenticity is a component of food and can be defined by the compliance of food to the referential genuine. The concept of authentic, defined by something original, true, undoubtedly etc. applied to food, certifies that these products are from a certain origin in concordance with standards and force rules and with the inscriptions of the presentation label.

The authenticity, as a part of quality components, must be certain and certified and every product must have a name accompanied by a set of legal features to avoid every type of confusions on the market.

Due the diversity of authentication criteria and the high number of products, the methodology of deceleration of authenticity and estimation of the amplitude of fraudulent products includes a series of methods and techniques of general/specific

investigation: chromatographic methods, spectroscopic methods, biochemical methods, immunological methods, AND analysis, electrophoretic methods, radiological methods, microscopical methods.

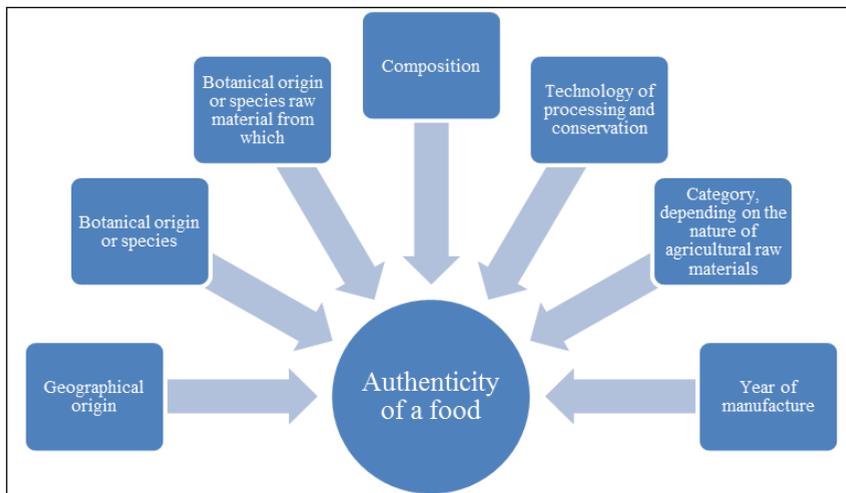

The criteria which define authenticity of food are numerous and variable from product to product (see fig.2) and the authentication and/or detection of possible frauds requires 3 steps:

**Figure.1:** The stages of detection possible fraud

Source: Bulancea, M. and Rupeanu, G., 2009

The processing of food data even from raw materials represents a basic link for ensuring the accuracy of the results. For this purpose, is required to make a sampling plan which details the way of sampling the data, for these samples to sufficiently representative for the product which is under investigation.

**Figure.2:** Defining elements for authenticity of food

Source: Mencinicopschi, G. and Raba, D., 2005

## **The traceability of food**

Food safety represents compliance of hygienic-sanitary in the process of production-distribution, for guaranteeing the health of population by consuming safe food in terms of sanitation, nutritional values and respecting the environment (Mencinicopschi G and Raba D., 2005).

Food safety can only be reached by the growth of quality and food services monitored through the whole food chain, an indispensable instrument being the achievement of realizing the traceability.

The management system of food safety it's found in ISO standards 22000 which specifies the requirements of the system in a food chain.

The transposition of this standard in Romania by the Law 150/2004 regarding food safety, represents the legal and juridical base for assuring a high level of consumer health protection and the interests of those towards food, considering the offer diversity, traditional products, correlated with the efficient operation of internal market.

The mentioned law defines traceability as being the identification possibility and following during all stages of production, processing, distribution, of food, animal food, of an animal dedicated to food production or a substance which follows or might be incorporated in food or animal food.

For commercial and food safety the monitoring of food is required from the producer to final consumer, this implying a series of complex solution and implicitly, and traceability assurance of the product according to the concept "from farm to table".

By the standard ISO 9000/2000 is defined that traceability is the ability to manage the history of a product, application or localization of an entity by recordings.

The traceability offers the possibility to reconstitute/follow the route course of a product from the beginning of his manufacturing until the consumer, through all phases of production, packing, conservation, transport, manipulation, depositing, and commercialization.

In the sphere of food, traceability makes bonds between raw materials, their origin, processing, distribution and their location after marketing.

The Codex Alimentarius commission by traceability emphasizes the capacity of following the course of food in different specific phases of production, processing and distribution.

The main elements which affect in certain mode the politics of an organisation regarding traceability are:

- ✓ monitoring the entire supply chain;
- ✓ objectives set by the organization to ensure food safety.

Traceability benefits resulting from:

- ✓ identifying sources of contamination;
- ✓ managing crisis situations;
- ✓ withdrawal from the market of products that may endanger the health or life of the consumer.

For a food production unit, traceability can be translated as "logistics management" and in this case there will be highlighted two key concepts: the traceability and the system of traceability as much (Pascu E., 2010):

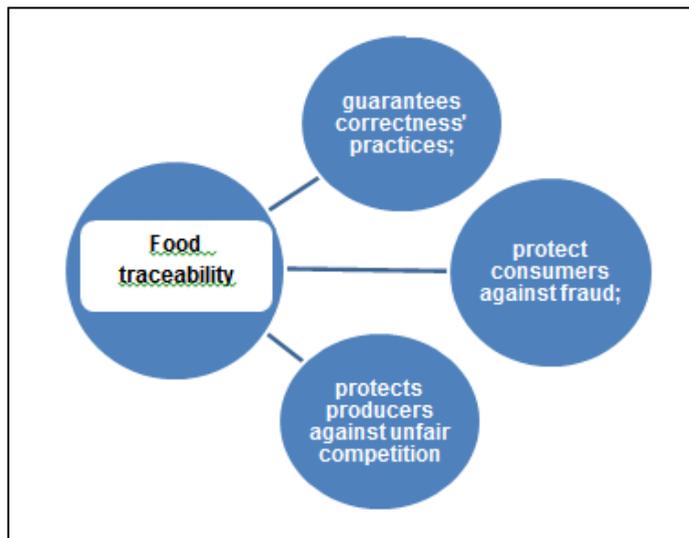

- ✓ traceability - the possibility to identify and follow by the entire course of all stages of production, processing and distribution of food, animal food, of

an animal dedicated to food production or a substance which follows or might be incorporated in food or animal food (according to Law no.150/2004);

- ✓ the traceability system, the total data and operations capable maintaining the informations needed of a product and its components during a part or the entire production and use chain (according S.R EN.ISO 22005).

Food traceability should cover basically two objectives:

- ✓ to provide information to users of the product;
- ✓ to contribute to food security by enabling, where appropriate, product withdrawal and recall nonconforming lots.

**Figure.3:** Benefits of food traceability

**Source:** European Commission, 2007

Traceability requirements in Article 18 of Regulation 178/2002 of the European Parliament are determined as follows (Pascu E., 2011):

- ✓ the traceability of food, pet food manufacturer or any other substance intended or expected to be incorporated in food or any other food products shall be established in all the stages of production and processing;
- ✓ food and feed operators must identify any person from whom did the food supply, feed, food-producing animals and any substance to be incorporated into food and also must have systems/procedures that will allow information to be made available to authorities on request;
- ✓ operators of food and feed business must have systems/procedures to identify other operators who have delivered these products. information will be provided to the competent authorities at their request;

- ✓ foods/feeds that are placed on the market or to be placed on the market within the European Union will be properly labeled / identified to facilitate their traceability.

## **Conclusions**

The customer protection was and continues to be one of the European essential values, fully reflected, over time, into community law.

At the proposal of European Commission is to be achieved by the end of the year 2013, an internal market more integrated and efficient, particularly in the retail sector, commercial agents, technologies and selling methods in retail markets in the EU, based on an equally high level of protection, competitive markets, open, transparent and fair, reliable products and services and not least commercial agents, especially the IMM to be able to sell products in the EU without barriers.

**Abstract:** *The activity of any economic entity is aimed at providing objects, works and services meant to fulfill certain social needs, as well as at achieving a certain level of profit which would enable the enterprise to maintain and/or develop in business. In order to reach these objectives, the offer of the enterprise should meet the demand of the market within which it activates in terms of: volume (how much it is demanded?), structure (what brands are demanded and what is their share in the total production?), rhythmicity (during what span of time?) and level of quality (does the offer of the entity meet the qualitative level demanded by clients?). The enterprise develops interconditioning relations with its external factors, namely clients, suppliers, the state, employees, shareholders, banks, the government and budgetary institutions; the degree to which their expectations are met reflects the efficiency of the activity undertaken. Among the main indicators of performance, one could cite the turnover and the added value that reflect the economic raise of the entity, conditions its strategic position and defines its place in relation to other competitors, within the branch of activity concerned. A high level of turnover and added value guarantees that the economic entity develops a profitable activity, that it is expanding and developing, a fact with consequences upon the main economic-financial indicators but also upon the efficiency of the activity of the economic entity. The main objectives of the present paper are to point out the dynamics of the indicators of volume of activity, of factors of influence and of their strategies of growth. In addition to that, the study tries to ground and analyse theoretical aspects by providing some practical examples based on real data obtained from an economic entity during the period 2008-2011, but also data published by the INSSE for the same period, in order to observe its evolution in relation to other evolutions from the sector concerned.*

**Keywords:** *turnover; volume indicators; methods of analysis; dynamics structure; strategies of growth; factors of influence.*

## **1. The system of value indicators reflecting the volume of the activity of production and marketing**

The activity of production and/or service provision exerts a decisive influence upon all aspects of economic activity – the volume and the schedule (brands) of production determines the specialization of the enterprise, its type of organization, the utilisation of capacities of production, of material and human resources. This segment of

activity also influences the financial results of the economic entity. The entire activity of an economic entity can be assessed through a system of volume indicators. The economic entity develops in a current and repeated manner operations of purchase, production and marketing which give content to its exploiting activity, an activity which, after all, is the basic activity of the economic entity. The efficiency of the exploiting activity and of the economic-financial performances that define the activity of the enterprise can be assessed mainly by indicators, both of volume, or physical, and of value. (Mironiuc, M., 2006). Physical indicators reflect in a real way the own effort of the enterprise in what regards the volume of its activity and they are not affected by price inflation. However, they can only be applied to entities with homogenous production and don't allow other activities to be included in the physical production (the production in course, semifinished products, industrial works) (Păvăloaia, W., 2002).

These shortcomings are surpassed through value units (costs, current and/or comparable prices), which also offer the possibility to obtain indicators aggregated through successive additions, regardless of the nature of production. The economic theory and practice offers a system of value indicators in order to assess the results of the activity of production and marketing of an enterprise, as well as the effects of the dimension of economic activity (Vâlceanu, Ghe. et. al., 2004. Some data sources useful to analyze these indicators are: The Profit and Loss Account, the table of intermediary balance accounts and data from the operative records of the enterprise. The table 1 presents the step-by-step formation of intermediary balance accounts, based on real data from the level of an economic entity and their evolution in time during the years 2008-2011.

**Table 1:** The system of volume indicators. Formation and evolution

Source: Real data at the level of an economic entity from the Account of Profit and Loss

The net turnover (CAN) highlights the dimension of the business log achieved by an economic entity in its relations with other partners. As an indicator of volume of the activity of an enterprise, the net turnover includes „sums obtained from sale of goods and service provision that fall into the category of current activities of the legal entity, after deduction of commercial discounts, of the added value tax, of other rates and taxes associated” (acc. to OMFP 3055/29.10.2009, M Of. al României nr.766/10.11.2009).

At the level of economic entities with an industrial profile, an increased share from the total of the net turnover belongs to the production sold ( $Q_v$ ), whereas a smaller share can be attributed to income obtained from the sale of goods ( $V_{VM}$ ), if the given entities own a chain of stores to market part of their products.. In the case of economic entities that function in the domain of distribution and marketing of goods, the greatest share (100%, if there are no discounts) from the total of the net turnover belongs to the income obtained from the sale of goods. Income from exploitation subventions associated with the net turnover ( $V_s$ ) and commercial discounts allotted (R) generally have insignificant shares and depend upon the capacity of the entity to attract subventions for investments (from the state or from various European institutions), while allotment of commercial discounts depends on the ability of negotiating with clients), but also on concrete conditions of market circumstances (in periods of crisis the purchasing power and the demand fall off, hence these discounts could exert a bigger influence on the turnover).

On analyzing the data from Table 1, we can observe that during the period in view the net turnover records a slow decrease in 2009 as compared to 2008, which is followed by increases in the next two years (respectively by 10,5% in 2010 compared to 2009 and by 15,6% in 2011 compared to 2010). As far as the entire period

analyzed is concerned, we could observe that the share of sold production within the total of turnover is dominant, due to the object of activity of the enterprise, which is the activity of production. So that, on composing elements, the production sold follows approximately the same evolution as the turnover (a fact which is, in fact, normal, because the production sold holds the greatest share within the turnover), while income from the sale of goods through the own chain of stores follows an ascending trend all along the period in view, with significant increases as compared to the preceding period. The economic entity analyzed grants discounts, insignificant in 2010 and 2011, but does not record income from exploitation subventions.

*The production obtained intended for delivery ( $Q_i$ ) or the production of manufactured goods* represents the direct and useful result of the producing industrial activity, expressing the value of products manufactured, of works executed and services provided during a certain period of time and which are to be sold. The production of manufactured goods can be calculated by using information from the accounting inventory. Although not included among indicators from the Account of Profit and Loss, neither among indicators presented in the table of intermediary balance accounts, the production obtained intended for delivery is an indicator useful to estimate the potential result of exploitation (profit or loss), because it offers better correlation with effort indicators in order to calculate the efficiency of the activity of the economic entity". (Vâlceanu, Ghe., et. al., 2004: 46-47). At the level of the entity analyzed, we can observe that this indicator follows the same trend as the sold production. Even if stocked production records a significant increase in 2010 compared to 2009 (by 771%), the period stockage on each year analyzed is still insignificant compared to the value of sold production, a favourable aspect since the interest of the entity is to sell, not to stock products.

*The production of exercise or global production ( $Q_{ex}$ )* highlights the dimension of the commercial activity of a productive enterprise both in its relation with third parties (clients) through *sold production* and *variation of stocked production*, on the one hand, and in its relation to itself through *immobilized production*, on the other hand. The production of exercise is an indicator specific to industrial units, measuring the global volume of the activity developed. It includes the value of goods and services "realized" by the enterprise in order to be sold, stocked or used for own needs. In the case of industrial enterprises, the production of exercise consists of the turnover to which adds the stocked, respectively the immobilized production. If industrial enterprises record great discrepancies between the moment of fabrication and of facturing, as well as significant values of the stocked and immobilized production, then the production of exercise provides a more faithful image of the activity of the enterprise than the turnover.

During 2008-2010 the production of exercise is identical to the production obtained intended for delivery, since there is no immobilized production recorded. This immobilized production is recorded only in 2011, but in an insignificant sum (197 thousands lei), the trend of the evolution of production deriving still from the sold production.

*The commercial margin (MC)* determines the performances of entities functioning in the domain of distribution and marketing and performances resulted from the commercial activity within own stores in case of enterprises from other domains. The commercial activity is represented by the purchase and resale of goods, which are considered goods purchased in order to be resold as such. The commercial margin

has to be dealt with gradually, according to the type of sales policy promoted by the enterprise and the type of the commercial activity.. From the Table 1, we can observe that the commercial margin follows an ascending evolution during the period in view, a significant increase being recorded in 2009 as compared to 2008, when the commercial margin doubles, due to increase of income from the sale of goods by 10% and decrease of expenses with goods by the same percent. One should also consider the fact that consequences of crisis could be felt in 2009, which either made a part of the population orient towards products purchased directly from the producer due to their purchasing power falling off, or it made income increase due to the appearance of a new brand of quality products (Gerovital, Aslavital). In the following years the commercial margin grows from one year to another, but against the background of greater increase of income from the sale of goods as compared to the rhythm of increase of expenses with goods.

*The industrial margin (MI)* represents the value newly created in the activity of production developed by an economic entity during a given period of time.. At the level of the productive entity the industrial margin contributes significantly in the formation of added value. From the Table 1 we can observe that the industrial margin maintains relatively constant in 2009 compared to 2008 (the index being 100,8%). This maintaining within parameters of the previous year took place against the background of decrease of the production of exercise (by 9,4%) through the sold production, but especially of intermediary consumptions (which decreased in a higher degree, by 16,3%). The industrial margin increases in the following two years (by 8% in 2010 compared to 2009 and by 11,6% in 2011 compared to 2010), due to the increase, approximately in the same degree, both of the production of exercise and of intermediary consumptions.

*The added value (VA)* expresses the increase or the plus value achieved by the entity by using factors of production in a transaction period. This increase in value, over the value of goods and services provided by third parties, is generated by activities of sale and marketing and consists of either the sum of the two margins, or the sum of earnings of factors directly or indirectly involved in the activity of the economic entity (employees and social organisms, the state, debtors, shareholders etc.). During the entire period analyzed, the added value formed by summing up the two margins, with greater share of contribution of the industrial margin compared to the commercial margin, follows an ascending evolution from one year to another, in relatively steady proportions in the last two years (by 11,3% in 2010 compared to 2009 and by 12,2% in 2011 compared to 2010).

*The result of exploitation (RExp)* appears as a result of rolling of flows of exploitation, including economic operations with specific, common and repetitive character. During the entire period analyzed, the result of exploitation takes the form of profit. However, this records a decrease in 2009 compared to 2008 against the background of greater decrease of the exploitation income (by 9,9%) as compared to the decrease of exploitation expenses (by 8,6%). In 2010, as compared to 2009, the exploitation profit decreases due to the higher rhythm of increase of exploitation expenses as compared to the exploitation income. The year 2011 brings a sudden change in the situation of the evolution of profit: it grows by 46,2% due to the greater rhythm of increase of exploitation income, as compared to exploitation expenses.

## **2. Correlative analysis of the dynamics of value indicators**

If we highlight correlations between the dynamics of the main indicators we can observe the way programs of production and marketing are grounded and also the way in which they are realized, as compared to programmed levels or to achievements from previous periods. On this basis, we can assess deviations (in absolute or in relative measures), their causes, but also provide measures to be taken in order to correct unfavourable situations. At the theoretical level, we can admit equality between all indicators presented, which shows the fact that, as related to a comparative base, there are steady proportions between elements that distinguish the given indicators, but such a situation cannot be met and it is not desirable, because, from one period to another, both quantitative and qualitative changes can be recorded between the elements that distinguish value volume indicators. The table 2 presents the main correlations between the dynamics of volume indicators

**Table 2:** Correlations regarding the dynamics and the static rate of volume indicators

Correlations/Rates	2008	2009	2010	2011
Correlations regarding the dynamics of volume indicators	-	$I_{QV} > I_{Qf}$	$I_{QV} < I_{Qf}$	$I_{QV} > I_{Qf}$
	-	$I_{Qf} = I_{Qex}$	$I_{Qf} = I_{Qex}$	$I_{Qf} < I_{Qex}$
	-	$I_{VA} > I_{Qex}$	$I_{VA} < I_{Qex}$	$I_{VA} < I_{Qex}$
The ratio between sold production and obtained production intended for delivery ( $Q_v / Q_f$ )	0.946	0.997	0.97	0.992
The ratio between obtained production intended for delivery and production of exercise ( $Q_f / Q_{ex}$ )	1	1	1	0.998
The ratio between added value and production of exercise ( $VA / Q_{ex}$ )	0.42	0.47	0.468	0.460

Source: Personal processing

On analyzing correlations between value indicators of the volume of activity, we can observe that the years 2009 and 2011 recorded an increase of the degree of valorification of production ( $I_{QV} > I_{Qf}$ ) against the background of reduction of the stocked production. The year 2010 records a reduction of the degree of valorification, because in this year stocked production records a superior rhythm of increase as compared to 2009. The fact doesn't have strong negative consequences because, even if growing very much in relation to the pervious years, stocked production records insignificant values compared to the sold production. Resources in order to improve performances could be find by analyzing the correlation between the index of added value and the index of the production of exercise, which fall into the ratio of  $I_{VA} < I_{Qex}$  in 2010 and 2011, meaning that in these years intermediary consumptions from third parties recorded higher increases than the production of exercise. Only the year 2009 records a favourable correlation, as in that year intermediary consumptions decreased more strongly. However, a closer analysis of the static ratio proves that the degree of valorification of production is rather high (close to 100%), while the added value is by about 50% over the value of intermediary consumptions from third parties.

### 3.The analysis of the net turnover – the main indicator of volume of activity

The net turnover represents the total income obtained from the commercial activity (through sale of goods manufactured) of an enterprise during a certain period of time. Certain authors assert that the turnover should represent about 85% of the exploitation income and at least 75% of the total income of the economic entity, whereas in what concerns the dynamics, it should present a tendency of real increase in order to ensure development and consolidation of the strategic position of the enterprise (Mironiuc, M., 2006: 59). These indicators reflecting the level of the turnover are also called operational indicators (Niculescu, M., 1997: 229), and are presented and calculated in the Table 3.

**Table 3:** Operational indicators of analysis of the turnover

Indicators	2008	2009	2010	2011
Net turnover $CAN=Q_V+V_{VM}+VS-R_a$	89850	86821	95929	110891
Expenses from the base activity (thousands lei)	33482	23895	29894	35670
Expenses from auxiliary activities (thousands lei)	0.00	0,00	0.00	0.00
Sale expenses (thousands lei)	25759	29445	30618	34576

Real rate of increase of turnover (%) $\Delta I_{CANReal} = \left( \frac{I_{CAN}}{I_p} - 1 \right) \cdot 100$	-	- 6,02	6,7	13,72
Indices of value of turnover in industry (the source INSSE domain "Fabrication of chemical substances and products") (%)	116,9	93,7	106,8	111,3

Source: Personal processing of data from the Account of Profit and Loss, Explanatory Note "Analysis of the exploitation result", of the economic entity analyzed and monthly Statistic Bulletins of the INSSE

By analyzing the evolution of the net turnover in current prices, we can observe it records a slow decrease in 2009 compared to 2008 (by 3,4%), but in the following years the situation improves and the turnover records increases by 10,5% in 2010 compared to 2009 and by 15,6% in 2011 compared to 2010. The dynamics of the turnover of the entity analyzed should be compared with the market dynamics, respectively to the dynamics of the sector of activity, in order to be relevant to establishing a strategy of development of the economic entity. If the sector is more dynamic than the economic entity, one can observe that the given enterprise will lose market interest, either due to the increase in superior rhythm of the volume of sales of the already existing competition, or due to the apparition of new competitors, or due to both causes combined. By comparing the index of the net turnover of the entity analyzed with the index of the value of turnover from the sector of activity in which it functions, we can observe that the situation is favourable, because even in the year when the turnover of the enterprise decreases, the sector records a stronger decrease (by an index of 93,7%), while in the other years the increase of the turnover of the enterprise is bigger than the sector increase, the entity being able to expand its business log.

The analysis of the critical turnover also points out relevant aspects in what regards the threshold of profitability of the enterprise, represented by that level of sales income necessary to fully cover exploitation expenses. At this level, the profit is equal to zero, while total expenses in relation to the volume of activity are grouped in fixed and variable expenses. We can observe the net turnover decreases in 2009, but the aspect cannot be seen as unfavourable, because the economic entity covers expenses with a smaller turnover than in the previous year (by 20% smaller than the critical turnover of 2008), thus obtaining a raw profit associated with the turnover by 159% bigger than in the previous year. The same fact is to a great extent due to the reduction of variable and fixed expenses, while the mean ratio of variable expenses decreases from 0,66 in 2008, to 0,61 in 2009. In 2010, despite favourable evolutions, the critical turnover increases more than the net turnover, and the entity records smaller raw profit associated with the net turnover (by 17% compared to 2009), against the background of the increase of variable and fixed expenses and of the mean ratio of variable expenses (at 0,63). The year 2011 reflects a situation improved as compared to the previous year, since the increase rhythm of the net turnover (115,6%) is superior to the increase rhythm of the critical turnover (107,4%),

the raw profit associated with turnover recording significant increases compared to the previous year (by 52,3%), against the background of steady maintaining of the mean ratio of variable expenses.

Since the turnover is expressed in current prices, a correct assessment of facts requires the adjustment of nominative indicators (current values) to the inflation rate corresponding to the sector of activity in which the economic entity functions, so that later in time the own effort of the economic entity could be pointed out. The data can be compared in time by deflating the indicator (deflated turnover). At the level of the entity analyzed, we can observe that the index of consumption prices for the category of goods marketed by the enterprise (hygiene articles and cosmetics), doesn't record significant increases from one year to another, this is why the real turnover is very close to the level of nominative turnover, which reflects the fact that the economic entity has obtained an increase of turnover from one year to another based on its efforts to improve quality and diversify the choice of brands, while the sale price grows rather for economic reasons than due to inflation. The only year when the entity recorded a real decrease (of - 6,02%) of the turnover was 2009, due to the reduction of the nominative value of turnover, as well as to the growth of consumption prices for the group of specific products, however, as we already pointed out, the entire sector in which the economic entity analyzed activates was affected in that year. The next two years record a real increase of 6,7% in 2010 and of 13,7 % in 2011, for the entire period analyzed (2008-2011) the mean rhythm of increase of the turnover being of 7,27%.

#### **4.Strategies of increase of the performance of the enterprise**

The ways to improve the performance of the enterprise should come from two directions: minimizing efforts and maximizing effects, or surpassing of the rhythm of increase of expenses (efforts) by the rhythm of increase of the income (effects). Considering the observations displayed above, we can highlight the following possibilities of increasing the economic-financial performance of the enterprise:

- *Reduction (optimisation) of costs* based on diminishing material and live labour expenses by: use, as complete and efficient as possible, of existing capacity of production; introduction of new equipment and technology, superior in output; increase of the fund of time effectively used by elimination of time losses of any kind;; provision on schedule with raw materials and materials in quantity and quality adjusted to the process of production; optimum dimensioning of stocks of raw materials, products in course of execution and finished products; increase of the level of qualification of the working force;, through measures of enhancing the productivity of work;
- *The increase of the volume of production* represents an indirect way of enhancing the performance of activity, because it acts indirectly, by reducing costs, as fixed and slowly variable costs do not grow or grow in a rhythm which is inferior to the increase of the volume of production;
- *The achievement of an efficient structure of production* must be correlated to the market demands and must follow the assimilation of new products, with enhanced performances, as well as the improvement of the structure on qualities of production and the achievement of an ISO 9000 certificate. An efficient structure of production is reflected in the level of the mean rate of profitability;

- *The acceleration of the speed of rotation* of resources, respectively the shortening of the duration of a circuit also has positive effects upon profitability, due to the fact that we obtain a bigger volume of profit, without needing to increase also the volume of resources.
- *The use of the price indicator* stimulates enterprises in order to ensure and increase profitability, but this can only be achieved in correlation with the increase of the qualitative level and of the complexity/diversity of products.

## 5. Conclusions

For any manager, the level of results obtained represents the measure of efficiency of the activity developed, and a part of this measure stands in reflecting the volume of activity and following its tendencies in time and in relation to other partners from the respective market. The production exerts a decisive influence upon all sides of the economic activity; this segment of activity influences to a great extent the financial results of the economic entity. Starting from the importance of the objectives of the activity of production, these should be followed both on the total of the economic entity and on its subdivisions. The program of production has to be followed not only in long intervals (year, semester), but also in shorter periods: trimester, month, decade, days. One should also never ignore the achievement of production tasks in terms of brands and structure, but mostly in terms of quality, so that the offer should meet the market demand.

The entity analyzed in this paper managed to obtain favourable and increasing results even in the period of economic recession, due to the strategy of development implemented. This strategy consisted in the accent placed on production (by diversifying the range of brands and improving the quality of existing products, by involvement in the activity of innovation through launching of new products, by making investments in machinery and equipment), but also on distribution (by opening agencies, purchasing fabrication licence for products acknowledged on the market, advertising by sustained marketing activity, notoriety given by the quality of products and the accessibility of prices, attracting of new retail contracts both in the country and abroad, the growth of quality and qualification of employees).

abadulescu@uoradea.ro*

**Abstract:** *Entrepreneurship is an active field of research, having known a major increase in interest and publication levels in the last years (Landström et al., 2012). Within this field recently there has been an increasing interest in understanding why some regions seem to have a significantly higher entrepreneurship activity compared to others. In line with this research field, we would like to investigate the differences in entrepreneurial activity among the Romanian counties (NUTS 3 regions). While the classical research paradigm in this field is to conduct a temporally stationary analysis, we choose to use a time series clustering analysis to better understanding the dynamics of entrepreneurial activity between counties. Our analysis showed that if we use the total number of new privately owned companies that are founded each year in the last decade (2002-2012) we can distinguish between 5 clusters, one with high total entrepreneurial activity (18 counties), one with above average activity (8 counties), two clusters with average and slightly below average activity (total of 18 counties) and one cluster with low and declining activity (2 counties). If we are interested in the entrepreneurial activity rate, that is the number of new privately owned companies founded each year adjusted by the population of the respective county, we obtain 4 clusters, one with a very high entrepreneurial rate (1 county), one with average rate (10 counties), and two clusters with below average entrepreneurial rate (total of 31 counties). In conclusion, our research shows that Romania is far from being a homogeneous geographical area in respect to entrepreneurial activity. Depending on what we are interested in, it can be divided in 5 or 4 clusters of counties, which behave differently as a function of time. Further research should be focused on explaining these regional differences, on studying the high performance clusters and trying to improve the low performing ones.*

**Keywords:** *entrepreneurship; cluster analysis; time series; regional clustering*

**JEL classification:** *L26; C38; R11*

## 1. Introduction

Entrepreneurship is a relatively new field of interest in economics research, its emergence occurring in the second half of the 20<sup>th</sup> century. Before that period, most of the research focused on the large enterprises, as they were seen as the engine of economic growth and innovation (Faria et al., 2010).

Due to recent technological development and economic instability, small enterprises are now 99% of the total number of companies in the European Union, providing 2/3 of the jobs in the private sector (Dodescu and Badulescu, 2009), having therefore turned entrepreneurship into a significant and independent research field.

Our paper aims at highlighting the differences in entrepreneurial activity among the Romanian counties (NUTS 3 regions), by using a time series clustering analysis to better understanding the dynamics of entrepreneurial activity between counties.

The paper is organized as follows: in the first part we briefly review the literature on entrepreneurship as endogenous factor of regional development and, particularly, on previous findings related to the way that entrepreneurial activity clusters on certain regions.

We review main studies and their findings on several regional clusters, focusing on most recent researches. In the second part we present the research methodology and selection and definition of variables. The main part is assigned to presenting the analysis itself and its main findings concerning the groups identified as clustering the entrepreneurial activity within Romanian counties. Finally, we briefly conclude and draw main directions to continuing studies.

## **2. Overview on literature about entrepreneurial activity and its clustering**

An important reason for studying entrepreneurship is that economic growth is strongly correlated with an abundance of small, entrepreneurial firms (Glaeser et al., 2010) and the causal relationship between the two could bring important information regarding growth models.

Defining entrepreneurship has proven to be a complex endeavor, as there are many opinions as to what exactly an entrepreneur is, and where the line should be drawn between entrepreneurial and non-entrepreneurial activity. Some definitions focus on the innovative aspect of the new enterprise, such as the classical definition given by Schumpeter, i.e. "the doing of new things or the doing of things that are already being done in a new way" (Schumpeter, 1947:151), while other researchers choose to use a more broad definition and include in this field all new privately owned companies, the entrepreneur becoming a person that either works for himself or that starts a new company (Van Der Sluis et al., 2008:803), and some even think of entrepreneurship as a new factor of production, in addition to the classical land, labor and capital ones (Cuervo et al., 2007).

The field of entrepreneurship has been investigated from multiple perspectives and theoretical points of view. The first approaches were close related to the psychological theories, and investigated the entrepreneur as a person, trying to determine the general traits and characteristics that differentiated him from the other businesspersons. The focus later widened to include company characteristics and even regional and country characteristics. The main theoretical models in this field focused on one or more of these levels, and can be divided into Economic, Psychological, Socio-Cultural and Managerial approaches (Veciana, 2007).

Theories of regional development can be generally divided into two categories (Martin and Sunley, 1998): theories that believe regions will inevitably diverge, as a consequence of economies of scale and agglomeration, and theories that believe regions will eventually converge, and differences between them should reduce in time as a consequence of imitation and complementarities (Garofoli, 2002).

Studies have shown that entrepreneurial activity tends to cluster, or agglomerate in certain regions, and that this might lead to a divergence effect. The assumed origins of entrepreneurial clustering are lower costs, better amenities and human capital in some areas (Glaeser et al., 2010). Another factor is the diffusion of information and capital to other companies upstream and downstream (Khan and Ghani, 2004).

This “spillover effect” in entrepreneurship has been investigated and confirmed in several studies (Anselin et al., 1997; Montoro-Sánchez et al., 2011). For instance in the case of USA the effect seems to be positive and limited to a 50 mile (~80 km) radius around the Universities and Research and Development (R&D) centers, and transcending state boundaries (Anselin et al., 1997).

From this perspective our paper is a macro-economical level analysis under the Economical approach, investigating the possible causes of differential regional entrepreneurial development at a county level. From a theoretical standpoint we are hoping to find evidence in support of the Theory of the endogenous regional development, in the sense that we believe the differences in regional entrepreneurial activity could be attributed to characteristics of the regions themselves and more specifically to various spill-over effects of transferring knowledge from universities and R&D institutes to the private sector leading to increased innovation, as suggested by some authors (Karlsson et al., 2009).

An early approach to regional clustering sought to compare countries and groups of countries, however more recently the unit of analysis has become much smaller, focusing on regions within countries and even on metropolitan areas. This development is attributed to the discovery that inter-country variance is most of the time smaller than intra-country variance (Martin and Sunley, 1996).

Some studies have investigated the clustering of entrepreneurial activity within several countries, and as shown in Table 1, their results indicate that entrepreneurial activity is far from being homogeneous within countries.

**Table 1:** A selection of previous studies in the field

Study	Country	Analysis level	Results
Delgado et al., 2010	USA	171 units	Significant differences by region and sector
Glaeser et al., 2010	USA	4 regions	Significant differences by region and sector
Kronthaler, 2005	Germany	97 regions	Significant differences by region
Rocha and Sternberg, 2005	Germany	97 regions	Significant differences by region
Unger and Chico, 2004	Mexico	3 regions	Significant differences by region and sector

### 3. Research methodology

Previous studies regarding entrepreneurial clustering at a geographic level have generally been interested in static clustering; that is they investigated the clustering of regions at a certain time point.

In contrast with this methodology, we believe it would be more informative to perform a time series geographic clustering analysis.

#### 3.1 Variables investigated

In the following section we provide detailed information regarding our variables, chosen indicator and information sources.

### **3.1.1 Entrepreneurship**

We choose to use as a measure of entrepreneurship the total number of new companies that have been open in a certain time frame, as suggested by other researchers (Van Der Sluis et al., 2008) and as done in previous research regarding Romanian entrepreneurial activities (Sipos-Gug, 2012).

For this purpose we collected the data regarding the total number of new enterprises registered every year, in every county (NUTS3 region) in Romania for the past decade (2002-2012). The data were collected from the National Trade Registry and are publicly available (ONRC, 2013).

### **3.1.2. Population – regional entrepreneurial supply**

We are also interested in the “supply of entrepreneurs” (Glaeser et al., 2010) in every region, and so we decided to investigate the number of entrepreneurs per region population.

This indicator was calculated as the total number of companies newly registered in a year in every county divided by the total population of the said county in that year. This indicator is only an approximation of the actual entrepreneurial supply, as several companies might well be founded by the same individual; however it is the best indicator we could construct.

Data regarding population were obtained from the National Statistics Bureau, and are publicly available (INS, 2013).

### **3.1.3. Academic activity**

As academic research and activity is believed to play an important role in entrepreneurial clustering, we collected data regarding the number of Universities focused on research in every county, and the results are shown in Table X. The data were collected from the official Romanian Classification of Universities (Monitorul Oficial al României, 2011).

**Table 2:** The number of Universities focused on research in every county

NUTS3 Region	Number of Universities
Bucuresti	11
Cluj	4
Iasi	4
Timis	4
Brasov	2
Constanta	2
Dolj	2
Sibiu	2
Bihor	1
Galati	1
Mures	1

Source: Monitorul Oficial al României, no. 637/2011

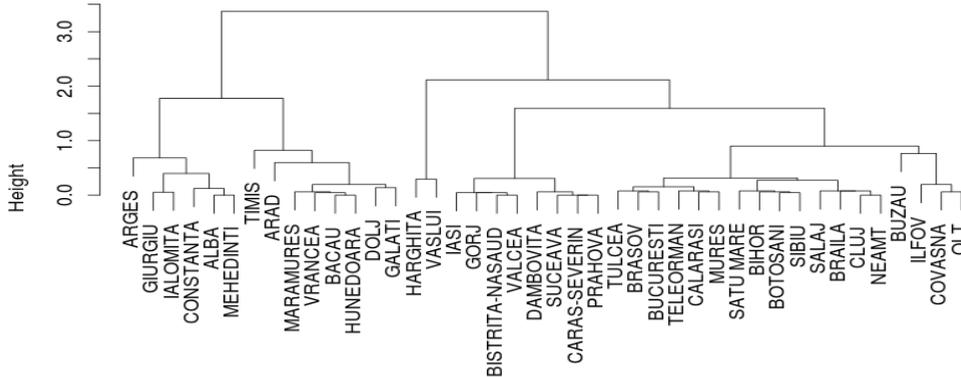

#### 4. Data analysis. Discussion and main findings

Data analysis was conducted using R 2.15.13. Cluster analysis was performed with the package pdc developed by Brandmaier (2011). While there are a high number of different methods proposed for cluster analysis of time series (Rani and Sikka, 2012), the PDC method is easy to use, equally reliable, and available freely as a R package.

##### 4.1. Cluster analysis A - entrepreneurial activity

The embedding dimension for the time series cluster analysis was chosen using the Minimum Entropy Heuristic (MinE) and set to 3.

Permutation distribution clustering (PDC) analysis was conducted with 3 embedding dimensions and 1 time dimension, and the resulting dendrogram is presented in Figure 1.

**Figure 1:** Dendrogram resulted from PDC of NUT3 Regions in function of yearly number of new enterprises (2002-2012)

We decided to choose the number of clusters as 5, as it seems to offer the best compromise between parsimony and obtaining detailed information with practical implications.

Table 3 shows the grouping of NUTS3 regions into clusters based on the evolution of new privately owned companies over the investigated time period. Regions marked with an “\*” have at least one Research University in them.

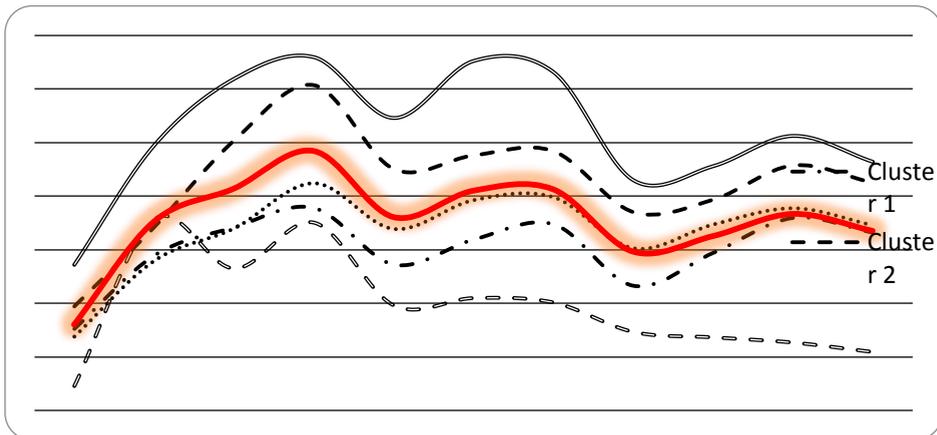

In order to test whether the presence of a Research University could be an explanation for the differences between clusters, we resorted to a chi-squared crosstab test. The resulting statistic  $\chi^2(4) = 2.771$  has an associated p value of 0.597, therefore we cannot claim that there are significant differences between clusters based on the presence of the universities.

In order to more easily describe the clusters we resorted to a graphical representation of the cluster centers as a function of time. From Figure 2 we can easily notice that Cluster A5 has a constant higher number of new companies per year than the other clusters. Cluster A2 seems to have an above average entrepreneurial activity, while Cluster A4 fits the average national distribution. Cluster A1 seems to have a slightly below average entrepreneurial activity, and then reach the average in 2012. Cluster A3 starts slightly below average, and after

reaching the average in 2003 shows a strong decline in entrepreneurial activity up to 2012.

**Table 3:** Clustering of NUTS3 regions as a function of yearly number of new enterprises (2002-2012)

Cluster A1	Cluster A2	Cluster A3	Cluster A4	Cluster A5	
Alba	Arad	Harghita	Bistrita-Nasaud	Bihor*	Ilfov
Arges	Bacau	Vaslui	Caras-Severin	Botosani	Mures*
Constanta*	Dolj*		Dambovita	Braila	Neamt
Giurgiu	Galati*		Gorj	Brasov*	Olt
Ialomita	Hunedoara		Iasi*	Bucuresti*	Salaj
Mehedinti	Maramures		Prahova	Buzau	Satu Mare
	Timis*		Suceava	Calarasi	Sibiu*
	Vrancea		Valcea	Cluj*	Teleorman
				Covasna	Tulcea

**Figure 2:** Graphical representation of cluster centers in Clustering A

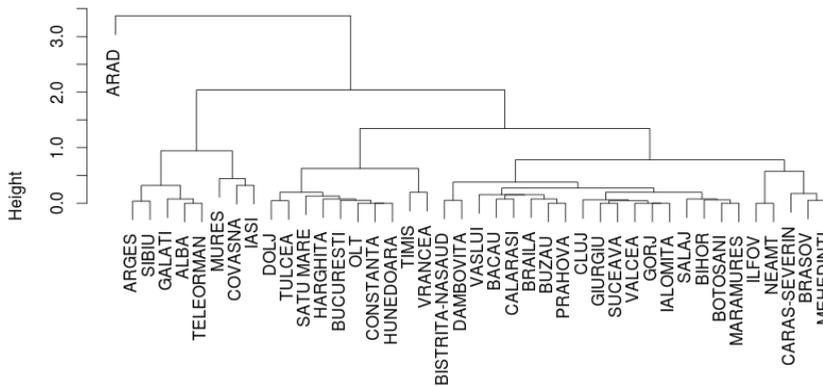

The distance between clusters varies from one year to another; however it doesn't seem to be influenced by the economic crisis and on the long term the low performance cluster seems to diverge more and more from the rest.

#### 4.2. Cluster analysis B - "entrepreneurial supply"

The rate of new privately owned companies per 1000 inhabitants was then analyzed using PDC in order to identify clusters of entrepreneurs.

The embedding dimension for the time series cluster analysis was chosen using the Minimum Entropy Heuristic (MinE) and set to 3.

Permutation distribution clustering analysis was conducted with 3 embedding dimensions and 1 time dimension, and the resulting dendrogram is presented in Figure 3.

**Figure 3:** Dendrogram resulted from PDC of NUT3 Regions in function of yearly number of new enterprises (2002-2012) per 1000 inhabitants

We decided to choose the number of clusters as 4, as it seems to offer the best compromise between parsimony and obtaining detailed information with practical implications.

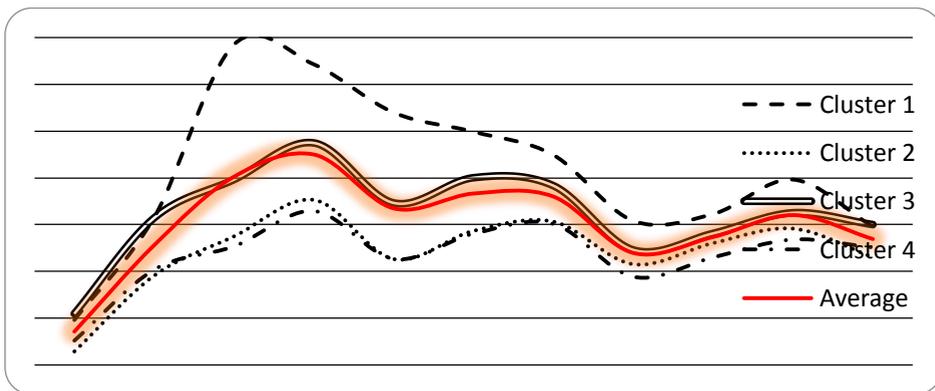

Table 4 shows the grouping of NUTS3 regions into clusters based on the evolution of the rate of new privately owned companies per 1000 inhabitants over the investigated time period. Regions marked with an “\*” have at least one Research University in them. In order to test whether the presence of a Research University could be an explanation for the differences between clusters, we resorted to a chi-squared crosstab test. The resulting statistic  $\chi^2(3) = 4.812$  has an associated p value of 0.307, therefore we cannot claim that there are significant differences between clusters based on the presence of the universities.

**Table 4:** Clustering of NUTS3 regions as a function of yearly number of new enterprises (2002-2012) per 1000 inhabitants

Cluster B1	Cluster B2	Cluster B3	Cluster B4	
Arad	Alba	Bucuresti*	Bacau	Gorj
	Arges	Constanta*	Bihor*	Ialomita
	Covasna	Dolj*	Bistrita-Nasaud	Ilofov
	Galati*	Harghita	Botosani	Maramures
	Iasi*	Hunedoara	Braila	Mehedinti
	Mures*	Olt	Brasov*	Neamt
	Sibiu*	Satu Mare	Buzau	Prahova
	Teleorman	Timis*	Calarasi	Salaj
		Tulcea	Caras-Severin	Suceava
		Vrancea	Cluj*	Valcea

Cluster B1	Cluster B2	Cluster B3	Cluster B4	
			Dambovită	Vaslui
			Giurgiu	

In order to more easily describe the clusters we resorted to a graphical representation of the cluster centers as a function of time. From Figure 4 we can easily notice that Cluster 1 has a rapid increase in the rate of new enterprises per 1000 inhabitants from 2002 to 2005, and then an above average but approaching average performance up to 2012. Cluster 3 has an average and slightly above average performance. Clusters 2 and 4 have a below average performance, with Cluster 2 slightly outperforming Cluster 4 over the majority of the investigated period.

**Figure 4:** Graphical representation of cluster centers in Clustering B

The distance between clusters varies from one year to another and like in the case of the clusters of section 4.1; it also doesn't seem to be influenced by the economic crisis. However in this case on the long term all the clusters seem to converge.

## 5. Conclusions and implications

Following the conclusions of similar studies of entrepreneurial clustering (see Table 1), we have also shown Romania is far from being one homogenous area when it comes to entrepreneurs and entrepreneurial supply. Some regions have a much higher entrepreneurial activity than others, and this tendency seems to be rather stable in time.

Therefore study also brings some information regarding the question of whether regional clustering is accompanied by a divergence or a convergence effect, which has been an active debate in current research (Nijkamp and Abreu, 2009). It would seem that from a time series point of view, there are alternating points of convergence and divergence. Further analysis is required; however from Figures 2 and 4 one can see this alternating pattern. Furthermore, while it would seem that on the long term convergence occurs regarding the supply of entrepreneurs, in the case of entrepreneurial activity as a whole one can actually see a tendency for divergence. We can conclude therefore that while convergence needs further study, it doesn't seem to be a linear function of time.

We could not replicate the results of previous studies regarding a relationship between entrepreneurial activity and the presence of a higher education institution research programs (Anselin et al., 1997; Montoro-Sánchez et al., 2011). This might suggest that in the case of Romania the spill-over effect might not be as strong in the case of other countries, however further research is needed.

Regarding the relationship between entrepreneurial activity and the “supply of entrepreneurs” proposed by some authors (Glaeser et al., 2010), the fact that the counties cluster differently on entrepreneurial supply than they do on general activity, might suggest that in our case this relationship is weak, however its significance was not tested, and further studies will be required before we can draw any conclusions. Our research has several implications for further research and policy making.

First of all, cluster analysis is primarily an exploratory tool, and as such we cannot assert as to why these differences have occurred, however now that we have identified them we can use this model to guide further research, such as case study or attempt for causal model building.

Secondly, future policy should take these clusters into account. They seem to be rather stable in time and as such very likely would require external intervention in order to prevent low performance clusters from remaining at the current level, or even from diverging further from the average. While the opinion regarding the possibility and success of cluster based policy change is disputed (Glavan, 2008), the free market mechanism alone, at least for the investigated period and in the case of Romania, does not seem to reduce the disparity between regions.

*petru.stefea@upcmail.ro*

*miofp75@yahoo.com*

**ABSTRACT** *The aim of this study is to test for the relevance of some financial ratios as descriptors of companies' financial status in explaining the evolutions of their business turnover. We are considering a data sample of 36 companies quoted on the Romanian capital market for a time span between 2007 and 2010. The predictive capacity of some significant financial ratios for the companies' business turnover is analyzed and a methodology for the evaluation of their financial status based on these ratios is advanced. We found that the predictive capacity of some relevant financial ratios for the dynamic of some quoted companies' turnovers is non-uniform across the two conventional sectors in which we have grouped these companies according to their field of activity. Based on these results, an synthetic indicator of the companies' financial status is constructed at the level of each individual sector and the non-linear correlation between this indicator and the business turnover is tested.*

**Key words:** financial ratios, financial status, quoted companies

*JEL classification:* M41

## **Introduction**

The study aims to reveal the potential connections between some relevant descriptors of companies' financial status and their results for some quoted Romanian companies in order to fill a gap in the empirical evidences of the financial status' impact on companies' performances in emergent markets. Due to the institutional, structural and functional particularities of these markets, it is expected to provide some insights about the involved transmission channels and to highlight some specificity of these. In the next section, a methodology designed to evaluate the predictive capacity of the selected financial ratios for the business turnover' dynamic and also to construct of a synthetic indicator of the financial status is advanced. Section 3 describes the data while Section 4 reports the results. Some conclusions are dropped and some further analytical directions are indicated in the last section.

## **Methodological framework**

For a preliminary evaluation of the predictive capacities of the financial ratios, we construct a binary variable designed to reflect the cases in which the companies are achieving better performances in terms of relative business turnover comparing with the averages outcomes in their sector:

$$BT^{binary}_{it} = \begin{cases} 1 & \text{if } BT_{it} > \overline{BT}_{jt} \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

Here  $BT_{it}$  is the (natural logarithm) business turnover of the company “i” in the current period “t” while  $\overline{BT}_{jt}$  stands for the average turnover of the sector “j”.

The main properties of the binary variable are reported in Table 1. It appears that these data are displaying a relatively significant degree of dispersion, with “fat tails” effects. This implies that the individual companies from each sector are behaving in a distinctive fashion in terms of their business outcomes. Thus, the choice of methodology should account for the distinctive patterns of business turnovers at the level of each sector.

**Table 1:** The main statistic characteristics of the business turnover (binary)

Observations	64	80

Source: own processing

Such specification of the binary variable allows for the identification of “over” and respectively “under” performances cases and for a further check of the capacity of financial ratios to discriminate between such cases. In other words, such frameworks allow an investigation of the connections between the companies’ financial status and their economic performances.

The next step implies the running of a binary equation with the next specification (with  $\mathbf{X}$  being the set of the considered explanatory financial ratios):

$$\Pr(BT^{binary}_i = 1 | X_i, \beta) = 1 - F(-X'_i \beta) \quad (2)$$

Here  $F$  is a continuous, strictly increasing function that takes a real value and returns a value ranging from zero to one.

In order to account for the mentioned heterogeneity of the data, we are using a particular specification of cumulative distribution function  $F$  based on the *extreme value distribution*:

$$\Pr(BT^{binary}_i = 1 | X_i, \beta) = 1 - (1 - \exp(-e^{(-X'_i \beta)})) = \exp(-e^{(-X'_i \beta)}) \quad (3)$$

If the considered financial ratios appear to be relevant for the prediction of the companies’ relative performances, then is possible to aggregate them in a synthetic descriptor of their financial condition and to further test the connections between such aggregate and the evolutions of business turnover.

A critical issue in the construction of such descriptor concerns the selection of the corresponding weights of financial ratios. At least three approaches can be considered: 1) the construction of an equiponderate measure with equal weights for each ratio; 2) the assignation of some ad hoc weights to reflect the perceived relative importance of the individual ratios in the description of the company financial status and, respectively, 3) the involvement of an multi-factorial analysis. Since the first two approaches can be affected by subjective biases, we are choosing to construct the synthetic descriptor of the financial status through a *principal components analysis*. *Principal components analysis* is a variable reduction procedure. Thus, it is similar in many respects to exploratory factor analysis but there are significant conceptual differences between these two procedures. Perhaps, one of the most important differences deals with the assumption of an underlying causal structure: factor analysis assumes that the co-variation in the observed variables is due to the presence of one or more latent variables (*factors*) that exert causal influence on these observed variables. In contrast, principal component analysis makes no such special assumptions about an underlying causal model and permits the analysis of more various empirical situations. Its central idea is to reduce the dimensionality of a set of interrelated variables, while retaining as much as possible from the variation which is present in dataset. The procedure is currently widely applied from climatology to economics, genetics, psychology or quality control (see for details Jolliffe, 2002).

This type of analysis models the variance structure of a set of observed variables by using linear combinations of the variables. These linear combinations, or *components*, may be used in subsequent analysis, and the combination coefficients, or *loadings*, may be used in interpreting the components.

The *principal components* of a set of variables are obtained by computing the eigenvalue decomposition of the observed variance matrix. The first *principal component* is the unit-length linear combination of the original variables with maximum variance. Subsequent *principal components* maximize variance among unit-length linear combinations that are orthogonal to the previous components.

From the singular value decomposition, a  $(n \times p)$  data matrix  $Y$  of rank  $r$  could be represented as:

$$Y = UDV' \quad (4.)$$

$U$  and  $V$  are orthonormal matrices of the left and right singular vectors, and  $D$  is a diagonal matrix containing the singular values.

More generally, one could write:

$$Y = AB' \quad (5)$$

$A$  is an  $(n \times r)$ , and  $B$  is a  $(p \times r)$  matrix, both of rank  $r$ , and

$$A = n^{\frac{\beta}{2}} U D^{1-\alpha}$$

$$B = n^{\frac{-\beta}{2}} V D^{\alpha} \quad (6)$$

Thus  $0 \leq \alpha \leq 1$  is a factor which adjusts the relative weighting of the left (observations) and right (variables) singular vectors, and the terms involving  $\beta$  are scaling factors where  $\beta \in \{0, \alpha\}$ .

The basic options in computing the scores  $A$  and the corresponding loadings  $B$  involve the choice of (loading) weight parameter  $\alpha$  and (observation) scaling parameter  $\beta$ .

In the *principal components* context, let  $\Sigma$  be the cross-product moment (*dispersion*) matrix of  $Y$ , and let perform the eigenvalue decomposition:

$$\Sigma = L\Lambda L' \quad (7)$$

Here  $L$  is the  $p \times p$  matrix of eigenvectors and  $\Lambda$  is the diagonal matrix with eigenvalues on the diagonal. The eigenvectors, which are given by the columns of  $L$ , are identified up to the choice of sign. It could be observed the facts that since the eigenvectors are by construction orthogonal,  $L'L = LL' = I_m$ .

There could be done some settings as  $U = YLD^{-1}$ ,  $V = L$ ,  $D = (n\Lambda)^{\frac{1}{2}}$ , so that:

$$\begin{aligned} A &= n^{\frac{\beta}{2}} YLD^{-\alpha} \\ B &= n^{-\frac{\beta}{2}} LD^{\alpha} \end{aligned} \quad (8)$$

$A$  can be interpreted as the *weighted principal components scores*, and  $B$  as the *weighted principal components loadings*.

Others detail of this procedure concerns an appropriate choice of the weight parameter  $\alpha$  and the scaling parameter  $\beta$  through which different *scores* and *loadings* with various properties could be constructed.

If the loadings of the first principal component are “closely enough” (i.e. there is not a disproportioned estimation of the relative importance of the individual financial ratios) then this component can be considered as an indicator of the companies’ financial status.

Such indicator can be further used in order to analyse the (short-run) impact of the changes in financial status on companies’ turnover and to highlight the potential structural changes in the involved linkages. Due to the existence of some important distinctions between sectors, the methodology should be distinctively applied for each individual sector.

An important issue of this evaluation concerns the fact that there are not, at least from an *ex ante* point of view, enough reasons to consider that the connections between financial status and business turnover have a linear nature. In fact, is more plausible to consider that these variables are linked in a non-linear fashion due to the complex involved causality. Thus, it is more adequately to check for the existence of such non-linear transmission channels. A possible way to perform such check is to consider the possibility of a non-linear co-trending linkage between the variables. Such nonlinear co-trading can appear when one or more linear combinations of the time series are stationary about a linear trend or a constant; hence, the series have common nonlinear deterministic time trends. The corresponding test is based on the eigenvalues of matrices constructed from the partial sum of the variables. It is nonparametric, since the non-linear trends and serial correlation processes do not need to be formally specified and is related to the Kwiatkowski et al. (1992) stationarity test for a univariate time series. There are at least two motivations for the construction of such a test (for a more detailed discussion about the relevance of this issue, see Bierens, 2000). Firstly, some long series perceived as unit root processes are displaying in fact a behavior more in accordance with a nonlinear

trend stationary hypothesis. Secondly, only few series that are not unit root processes still behave like co-integrated processes, in that the series move together over time in a similar way. But co-integration is only possible for unit root processes, thus, another approach is necessary.

The test statistic for the existence of such co-trending relationship as proposed by Bierens (2000), is  $\lambda_r$  for  $r = 1$  through  $k$ , where  $r$  is the number of co-trending vectors under the null, and  $k$  is the number of variables. The alternative hypothesis is that there are  $r - 1$  co-trending vectors. The test procedure also gives estimates for the co-trending vector parameters. More analytical, let  $y_t$  being the demeaned and possibly de-linear-trended vector of variables, and define:

$$\hat{M}_1 = \left( \frac{1}{n} \right) \sum_{t=1}^n \hat{F} \left( \frac{t}{n} \right) \hat{F} \left( \frac{t}{n} \right)^T,$$

$$\hat{F}(x) = \left( \frac{1}{n} \right) \sum_{t=1}^{\lfloor nx \rfloor} y_t, \text{ if } x \in \left[ n^{-1}, 1 \right], \hat{F}(x) = 0 \text{ if } x \in \left[ 0, n^{-1} \right]$$

$$\hat{M}_2 = \left( \frac{1}{n} \right) \sum_{j=s}^n \left( \sum_{j=0}^{s-1} \frac{1}{s} y_{t-j} \right) X \left( \sum_{j=0}^{s-1} \frac{1}{s} y_{t-j} \right)^T \quad (9)$$

Then it is solve:

$$\left| \hat{M}_1 - \lambda \hat{M}_2 \right| = 0 \quad (10)$$

Taking the ordered solutions of this, the test statistics are calculated as:  $n^{1-\alpha} \hat{\lambda}_r$ .

## Results and comments

Table 2 shows the estimated binary equations parameters. One of the most striking results appears to be the clear inter-sectors cleavage in the existing associations between the considered financial ratios and the business turnover. While for sector "A" all the corresponding coefficients appears to be statistically significant, for sector "B" only the coefficient of the fixed-to-total assets ratio is relevant. Thus, for sector "B" the model should be re-specified by dropping out the non-relevant explanatory variables and including others. Since the companies from this sector are typically characterized by an disequilibrium at the level of the ratios between their own and, respectively, borrowed financial resources, an appropriate choice of such alternatively explanatory variable can be for instance the total equity plus short-term liabilities-to-total liabilities ratio as a proxy of the companies' financial structure. Indeed, accordingly to the results reported in the last column of Table 2 this ratio is together with the fixed-to-total assets ratio negatively and statistic significantly associated with the business turnover in sector "B". It can be argued that the companies from sector "B" are more sensitive to the need for borrowed financial resources since their own resources are frequently insufficient to sustain the investments programs and the business expansion. And, as Clementi and Hopenhayn (2006), as well as Almeida and Campello (2001), argue, borrowing constraints have important implications for firm growth and survival. One of the key

arguments is that such constraint arises as a feature of the optimal long-term lending contract, and that such constraints relax as the value of the borrower's claim to future cash-flows increases. A similar line of argumentation is considered in Gilchrist and Himmelberg (1994) which found evidences that for firms with only limited access to capital markets (as indicated by lack of participation in public debt markets) investments (and, correlatively, the engaged volume of financial resources) appears to be "excessively" sensitive to fluctuations in cash flow.

Source: own processing

Also, for sector "A", these results highlight that the largest impact on business turnover is exercised by operating results-to- total assets while the smallest one is corresponding to the fixed-to-total assets ratio. The total equity- to -total liabilities ratio appears to have a negative impact on short-run turnover dynamic as reflecting the importance of a *financial leverage effect* for the companies from this sector. The binary equation also allows an estimation of the model predictor capacity through the so-called *classification table*. The fraction of observations that are correctly predicted is termed *sensitivity*, while the fraction of observations that are correctly predicted is labelled as *specificity*. The content of such classification is displayed in Table 3 with prediction results based upon expected value calculations.

Source: own processing

In the lower right-hand table, we can compute the expected number of  $BT^{binary} = 0$  and  $BT^{binary} = 1$  observations for a model estimated with only a constant. For this restricted model,  $E(BT^{binary} = 0)$  is computed as  $n(1-p)$ , where  $p$  is the sample proportion of  $BT^{binary} = 1$  observations. A classification is labelled as "correct" when

the predicted probability is less than or equal to the cut-off (80% in our estimation) and the observed  $BT^{binary} = 0$ , or when the predicted probability is higher than the cut-off and the observed  $BT^{binary} = 1$ .

Overall, the estimated model predicts for sector "A" 76.22% of the observations (73.42% of the observations with dependent = 0 and 78.53% of the observations with dependent = 1) correctly. It appears that the levels of *sensitivity* and, respectively, *specificity* for our model are almost the same, implying that it can discriminate both „extreme” and „regular” cases. The gain in the number of correct predictions obtained by moving from the right table to the left table provides a measure of the predictive ability of our model. Roughly, there is in the case of sector "A", an improvement of 52.01% over the constant probability model with our estimation. The *Goodness-of-Fit* tests (*Hosmer-Lemeshow*) compare the expected fitted values to the actual values by group. If these differences are "small enough", the model is fitting the data adequately. The values of these tests, also reported in Table 3, suggest that this is the case with the binary specification for sector "A".

However, for sector "B" the predictive capacity of the considered financial ratios is poorer. In the case of this sector, the re-specified model predicts overall correctly only 55.34% from the observations (62.21% of the observations with dependent = 0 and 45.05% of the observations with dependent = 1). Also, the improvement over the constant probability model is far lower (only 6.97%). Finally, the value of the *Hosmer-Lemeshow* suggests that even the re-specified model predicts less adequately the data comparing with the case of sector "A".

Based on these preliminary results, it can be argued that the companies from the two sectors are operating in specific business conditions and with different structural and functional elements. Thus, the impact exercised on the evolution of their business turnover by the financial conditions appears to be a distinctive one with particular transmission channels involved.

**Table 4:** Principal components analysis

The first section of Table 4 summarizes the eigenvalues, showing the values, the forward difference in the eigenvalues and the proportion of total variance explained. Since we are performing principal components on a correlation matrix, the sum of the scaled variances for the four (two in the case of sector "B") explanatory ratios used to describe the financial conditions for the companies included in sector "A" is equal to 4 (respectively 2 in the case of sector "B"). The first principal component accounts for 78% of the total variance of (98% in the case of sector "B"), while the second accounts for 11% (2%) of the total. The first two components account for over 89% (100%) of the total variation.

For both sectors, the second section describes the linear combination coefficients. It can be noticed that the first principal component (labelled "PC1") is a roughly-equal linear combination of all four (two) financial ratios. Thus, in both cases, it might reasonably be interpreted as a global indicator of the companies' financial status. Once such indicator of financial status is constructed based on principal components methodology, it is possible to carry out a more detailed analysis.

The scatter plot from Figure 1 suggests that the relationship between the financial status indicator and business turnover is a non-linear one (somehow with a "U" style shape for sector "A") and display a distinctive pattern for each sector. So, it is necessarily to consider a non-linear approach to the analysis of this relationship.

However, is the tests for the existence of a co-trending relation between business turnover and the proposed indicator of the companies' financial status is performed, it appears that there can be highlighted the existence of a co-trending vector in the case of sector "A" but of two such vectors in the case of sector "B". In other words, for sector "B" both variables are stationary and no co-integration / co-trending relationship can be considered.

**Table 6:** Tests of the null hypothesis that there are  $r$  co-trending vectors against the alternative that there are  $r-1$  co-trending vectors

**Sector "A"**

$r$	test statistic	10% critical region (conclusion)	5% critical region

**Conclusion (at 10%):  $r=2$**

Source: own processing

The existence of the co-trending vector between financial conditions and growth allows in the Bierens' methodology the decomposition of non-linear trend in growth. This can be done based on the fact that one can write  $F(x) = Q_2 Q_2' F(x)$ , where  $Q_2$  is the matrix of orthogonal eigenvectors of  $M_1$  corresponding to the positive eigenvalues. The vector  $Q_2' F(x)$  can be interpreted as the vector of common cumulative nonlinear trends.

Similarly,  $F'(x) = Q_2 Q_2' F'(x)$ , where  $Q_2$  is the matrix of orthogonal eigenvectors of  $M_2$  corresponding to the positive eigenvalues. The vector  $Q_2' F'(x)$  can be interpreted as the vector of common nonlinear trends.

Thus, for sector "A" we have:

Common cumulative nonlinear trend =

$$-0.151 \times \text{Component of } F(t/n) \text{ corresponding to FINANCIAL STATUS INDICATOR} \\ +0.98 \times \text{Component of } F(t/n) \text{ corresponding to BUSINESS TURNOVER}$$

Common nonlinear trend =

$$-0.06 \times \text{Component of } F'(t/n) \text{ corresponding to FINANCIAL STATUS INDICATOR} \\ +0.99 \times \text{Component of } F'(t/n) \text{ corresponding to BUSINESS TURNOVER}$$

Overall, these results shows that for sector "A" the proposed indicator of the companies' financial status form a non-linear relationship with the dynamic of business turnover whiles for sector "B" such relationship cannot be evidenced.

## Conclusions

This study is focused on the relations between the financial conditions characteristic for a set of Romanian quoted companies and the dynamic of their business turnover. The predictive capacity of some significant financial ratios for the companies' business turnover is analyzed and a methodology for the evaluation of their financial status based on these ratios is advanced. We found that the predictive capacity of some relevant financial ratios for the dynamic of some quoted companies' turnovers is non-uniform across the two conventional sectors in which we have grouped these companies. While for the companies with tertiary and quaternary activity the operating results-to- total assets ratio together with current -to -total assets and total equity-to-total liabilities ratios with appears to be relevant one in explaining the evolutions of their results, for the companies with primary and secondary activity only the fixed-to-total assets ratio and the structure of their financial resources displays statistical relevance. Based on these results, an synthetic indicator of the companies' financial status is constructed at the level of each individual sector and the non-linear correlation between this indicator and the business turnover is tested.

The study reveals some important inter-sectors differences in the nature, amplitude and relative importance of the involved transmission channels. Several explanations can be advanced for such differences.

Firstly, it can be argued that there is certain inter-sectors scale-differential effect with the companies from sector "B" usually displaying a larger scale and different organizational and functional structures comparing with the ones from sector "A". Such effect can leads to distinctive restrictions in the configuration of the companies' financial architecture and particular financing requirements.

Secondly, the companies from the two sectors display individual financial profiles with divergent own-to-borrowed financial resources ratios. Thus, the weighted costs of borrowed capital as well as the level and structure of this capital are influencing in particular manners the companies' results. Also, it can be presumed a non-uniform magnitude of the financial leverage effect between sectors.

Thirdly, the companies from the two sectors are operating in specific market environments with non-uniform efficiency of allocation and prices mechanisms and distinctive relationship between supply and demand. Fourthly, it is plausible to consider that due to imperfect information issues the decisions adopted by the managers from the two sectors are facing various moral hazard, adverse selection and residual loses issues which affects their companies' financial and economic performances.

This study does not explicitly address such explanations. Thus, further analyses are required for a better understanding of the involved transmission channels of the financial status' impact on companies' evolutions.

***SUB-SECTION: ECONOMIC STATISTICS AND MODELLING***

## A MODEL TO MINIMIZE MULTICOLLINEARITY EFFECTS

**Baciu Olivia, Parpucea Ilie**

*The department of Statistics, Mathematics and Forecasting, Faculty of Economics and Business Administration, Babes-Bolyai University, Cluj-Napoca, Romania  
oli\_baciu@yahoo.com*

**Abstract.** *Multicollinearity implies near-linear dependence among regressors and is one of the diagnostics that harms enough the quality and the estimation of the regression models. Among the effects of multicollinearity can be mentioned that parameter estimates could lead to opposite signs or the variables turn out to having insignificant coefficients although it is known from theory or reality that the relationship exists. Also, when other variables are included or removed from the model this can affect the parameter estimates. Usually, multicollinearity is measured with the help of Variance Inflation Factor. A value greater than ten indicates severe multicollinearity in the model. Different approaches are known to reduce or eliminate multicollinearity effects but some of them are not always applicable due to data. The most used methods include addition of more data or elimination of the variable that is highly correlated with other independent variables or the use of the Ridge Regression. In addition to the well known and used models it is proposed here a new approach for the multicollinearity reduction. This method implies creating an index variable as a linear combination of the highly correlated ones. The index coefficients are selected under specific constraints imposed on the variables such that the new variable becomes highly correlated with the response variable but not with the independent ones. The best coefficients can be chosen out of the solution domain using an optimization program. In the new model, the highly correlated variables are replaced by the index one. The quality of the new model is improved by reducing or even eliminating the effects of multicollinearity. The regression model is expected to yield proper estimates. Also, VIF returns appropriate values, lower than ten. The method is exemplified on the BRD stock portfolio. Multicollinearity was eliminated, as showed by a value of one of the VIF and the model is expected to improve.*

**Keywords:** *multicollinearity, regression model, index variable*

**JEL classification:** *C20, C51, C58*

### **1. Introduction**

Reality has to be modeled using statistical tools by creating models that include those variables that can express it the most accurate. The question that arises is which variables should be included to benefit the most for the purposes of the analysis. What happens when these variables help in explaining the reality but they influence each other?

The purpose of this article is to propose a remedial measure method that fixes the problem of multicollinearity without excluding any explanatory variables from the model. The originality of the method is that it allows keeping in the model all the variables that are highly correlated as a new variable, which is a linear combination of them. This single index can be constructed when two or more predictor variables are highly correlated and are revealing properties of a common feature. In the new model, the multicollinearity will be reduced or even eliminated.

In practice it is difficult to find data that does not contain extreme observations and is perfectly related. Also, the included variables may help in reducing the remaining variation of the dependent one but they can create near-linear dependence among the regressors. These two approaches are not always easy to use. Other techniques used to reduce the effects of multicollinearity are Ridge Regression or Principal Component Analysis.

## **2.Literature review**

Multicollinearity and how to overcome the deficiencies of a model being affected by it has been widely discussed by the theoreticians. Different approaches were proposed over time, some of them being used and applied today. In practice, there are several used methods to fix its effects. Among these methods, can be mentioned data elimination or addition, Ridge Regression or techniques related to Principal Component Analysis. In most cases, economical practice imposes to keep all the variables in the model for a better transposition of the reality. In other cases, there is no more data to add in order to balance the sample lack of information.

A large discussion about multicollinearity detection and how to approach it depending on the point of view of an econometrician or a computer programmer is presented in Farrar & Glauber (1967).

A different approach from the generally used methods is proposed by Conklin & Lipovetsky (2003). This method assumes a change in the correlation matrix by creating a new matrix of the same structure. The negative and large in absolute value correlations are replaced in the new matrix by the opposite sign values. In such way, the only negative values will be the ones with small absolute values.

O'Brien (2007), suggest combining variables into a single index as a measure of multicollinearity reduction but it does not indicate how to estimate the coefficients of the linear combination.

Chen (2012) is taking care of the "implausible estimates" caused by the presence of multicollinearity in a modern approach. It is using external informations, given by the theory and reality, combined with the statistical confidence region. "Based on a priori knowledge" it can be chosen "the most reasonable set of coefficients inside the confidence region". These coefficients will be significant because "they are highly consistent with the data".

## **3.Multicollinearity**

Construction of regression models has been a well researched theme over time. The key for a well done study is a well done constructed model. Each step in the strategy of building a model should be carefully inspected. A sensitive issue is the model selection. According to Kutner et al. (2005), the selection of a regression model depends mostly on the diagnostic results and multicollinearity is one diagnostic that can harm enough the model.

Highly correlated predictor variables do not damage the prediction but they do have an impact on the parameter estimates of the regression models. Due to multicollinearity, variables can have statistically insignificant coefficients though there is a relation between the dependent and the set of independent ones. It can also lead to parameter estimates with opposite sign than expected from theory or reality. When predictor variables are added or removed there are important changes in the estimated parameters.

When predictor variables are highly correlated, the interpretation of the regression parameters is affected. The usual interpretation that an increase by one unit of a parameter when holding the others constant leads to a change of the expected value of the dependant variable does not apply in the presence of multicollinearity.

The widely used method in multicollinearity detection is the Variance Inflation Factor. A large value of VIF is used as an indicator of a severe multicollinearity. According to Kutner et al. (2005) a VIF value exceeding 10 suggest severe multicollinearity and the same is considered according to Hair et al. (1995), Mason et al. (1989), Freund et al. (2006). But the choice of a significant threshold has to be made regarding other factors that influence the stability of the estimates of the  $i^{\text{th}}$  regression coefficients and VIF values should not be fixed a priori to some specific values, according to O'Brien (2007) and Freund et al. (2006). Other authors suggest identifying a severe multicollinearity in the model using the orthogonality of the variables. According to Farrar and Glauber (1967), the model is affected by multicollinearity if the variables are not orthogonal.

To overcome the effects of multicollinearity, some of the measures that are taken are either to add more data or to eliminate the variable that creates dependence among the regressors. Often, the predictor variables cannot be excluded from the model because they highlight the essence of the real situations. Elimination of key explanatory variables can lead to biased estimators of the regression coefficients. Addition of more data is used to diminish the standard errors of the parameters but this is not always possible. Another technique used is the Ridge regression. It allows biased estimators of the regression coefficients but reduces the level of multicollinearity.

Considering the reasons why one should be careful when adding or eliminating explanatory variables, a method of multicollinearity reduction without variable elimination is introduced in this article.

#### 4. Model description and estimation

The following linear model is considered:

$$r_t = \alpha + \beta R_t + \varepsilon_t \quad (1)$$

where  $R_t$  and  $r_t$  are two stationary time series variables and  $\varepsilon_t$  is the error term. If the time series are not stationary, they have to be made stationary.

In most cases one variable is not enough to explain the variation of the dependant variable and more predictor variables should be included. If the predictor variables are highly correlated it leads to the appearance of multicollinearity in the model.

Considering that one predictor variable does not explain well the model (1), let introduce in the model two new stationary time series variables  $X_t$  and  $Y_t$ , characterized by:

$$\begin{aligned} cov(X_t, Y_t) &> 0 \\ cov(r_t, X_t) &> 0 \\ cov(r_t, Y_t) &> 0 \end{aligned}$$

The fact that the covariance between the new variables is positive implies collinearity in the model. This can affect the model by reducing the stability of the parameter

estimates or by inflating the standard errors. The covariances between the dependant variable and the two new variables are also greater than zero, which implies that the new variables influence the explained one. In the new created model,

$$r_t = \alpha + \beta R_t + \gamma X_t + \delta Y_t + \varepsilon_t \quad (2)$$

if  $\text{corr}(X_t, Y_t) \gg 0$  is relatively high is a first hint that the multicollinearity phenomena is present in the model and could bring damages to its quality. In such conditions, theory suggests that a very easy to work with method is to eliminate one of the highly correlated variables  $X_t$  or  $Y_t$  or add more data if possible.

The proposed method allows keeping all the variables that are significant in the model. In most cases the variables kept in the model are the ones that explain much of the variation of the response variable.

The question that arises is if there are plausible conditions under which a combination of the two explanatory variables could eliminate or reduce the collinearity in the regression model. It is important that independant variables to be correlated with the dependant variable but the independant ones not highly correlated among themselves.

The following linear combination of the two variables is considered:  $Z_t = aX_t + bY_t$ , where  $X_t$  and  $Y_t$  are stationary time series.

Now, are there any real values for the parameters a and b such that  $\text{cov}(R_t, Z_t)$  to be relatively small and  $r_t$  and  $Z_t$  to be highly correlated?

The assumption used is that the covariance among the regressors has to be lower than the minimum of the covariances among the pairs of the explanatory variable introduced in model (1) and each of the new introduced variables in model (2). These covariances have to be low. If covariances are negative values, in the below inequalities, their values will be considered in absolute values.

$$\text{cov}(R_t, Z_t) < \min\{\text{cov}(R_t, X_t), \text{cov}(R_t, Y_t)\}$$

Simple computations lead to:

$$\text{cov}(R_t, Z_t) = a\text{cov}(R_t, X_t) + b\text{cov}(R_t, Y_t)$$

The minimum of the covariances is denoted by m. The above inequality becomes:

$$a\text{cov}(R_t, X_t) + b\text{cov}(R_t, Y_t) - m < 0 \quad (3)$$

By solving inequality (3) it can be chosen from the solution domain those values for a and b such that  $\text{cov}(R_t, Z_t)$  to be small.

In order for  $Z_t$  to be a factor influencing the variation of the dependant variable  $r_t$ , in the model has to be kept those values of a and b such that the influence of the new variable on the dependant one to be high. This means that the following inequality must hold:

$$\text{cov}(r_t, Z_t) > \max\{\text{cov}(r_t, X_t), \text{cov}(r_t, Y_t)\}$$

The maximum of the two covariances is denoted by  $M$ .

The above inequality is a condition that allows to keep  $Z_t$  as a variable in the model. After straightforward computations, the above inequality becomes:

$$acov(r_t, X_t) + bcov(r_t, Y_t) - M > 0 \quad (4)$$

By solving (4) can be chosen those values for  $a$  and  $b$  such that  $cov(r_t, Z_t)$  to be high. Choosing the values for  $a$  and  $b$  is reduced to solving the system of linear inequalities (3) and (4) by classical methods. From the domain of solutions, any pair of solutions should reduce the effect of multicollinearity. So, solving the sistem of inequalities allows to keep those values for  $a$  and  $b$  that helps reduce the multicollinearity from the model by reducing the covariance between the predictor variables and increasing the covariance between the dependent and independent ones. With  $a$  and  $b$  known, the index variable can be computed.

Introducing  $Z_t$  in the model as the new variable it gives:

$$r_t = \beta_0 + \beta_1 R_t + \beta_2 Z_t + \varepsilon_t \quad (5)$$

Finally, we can return to the initial variables by multiplying them with the corresponding  $a$  and  $b$ :

$$r_t = \beta_0 + \beta_1 R_t + \beta_2 a_0 X_t + \beta_2 b_0 Y_t + \varepsilon_t \quad (6)$$

Model (6) is in fact a model that allows to keep all the needed explanatory variables without having highly correlated explanatory variables in the model. One model building process step, multicollinearity diagnostics is now exceeded.

## 5. Example

To exemplify the proposed method, it is considered the case of the stock market portfolio BRD over the period January- April 15<sup>th</sup> 2013, by creating a model of the number of daily transactions. In the mentioned period is a total of 63 observations. The stock portfolio BRD is traded on the Bucharest Stock Exchange, which has the main index BET. In the below model is verified if the index of the market has an influence on the number of daily closed transactions. It is expected that the market index to have an influence on the number of closed transactions. The estimated linear model in Stata is:

$$trans = 996.51 - 0.164BET \quad (7)$$

where:

- $trans$  represents the number of daily closed transactions
- $BET$  is the Bucharest Exchange Trading Index ( RON Index Points)

As expected, the index variable  $BET$  help in explaining the number of closed transactions, by explaining 6% of its variation. The low proportion can be due to the chosen period, which offers an economical and political environment that does not allow high performances on the Romanian stock market. When the index  $BET$  increses by one unit point, the number of closed transactions are expected to lower

with 0.16 transactions. The response variable variation can be better explained if more appropriate variables are included in the model. In practice, the number of closed transactions is influenced by several factors, among which can be mentioned: price of the portfolio, volume of the transactions, performance of the stock market, performance of the portfolio and many others.

Since the model is explained in a low proportion by only one variable, two new variables are introduced. These variables are considered here as volume of the transactions and the value of the closed transactions. These two variables are chosen this way because they are highly correlated and the proposed model can be better exemplified. Usually, the variables that create the multicollinearity phenomena in the model are highly correlated but not as high as the ones mentioned.

When the two new variables are included in the model, the simple linear model becomes:

$$trans = 861.64 - 0.14BET + 0.62vol + 0.186val \quad (8)$$

where:

- trans represents the number of daily closed transactions
- BET is the Bucharest Exchange Trading Index (RON Index Points)
- vol is the volume of trades (x1000)
- val is the value of the trades (x1000 RON)

All the model parameters are significant at a 10% level of significance and were estimated using Stata software. For the given data, the model with three independent variables explains better the variation of the number of closed transactions, which is 42% compared to 6% explained only by the stock index. The model is better explained using three and not only one explanatory variable.

**Table 1:** Correlation matrix

	trans	BET	vol	val
trans	1			
BET	-0.23	1		
vol	0.52	0.09	1	
val	0.51	0.10	0.99	1

It can be seen from the above table that the two new introduced variables are highly correlated among themselves, which suggest the presence of multicollinearity in the model. They are also medium correlated with the response variable, meaning that these two variables help in understanding the response one. Multicollinearity is confirmed by the VIF values, which exceeds by much the threshold values.

**Table 2:** VIF values

Variable	VIF
vol	1144
val	1146
BET	1

The proposed method indicates that the problem of multicollinearity can be fixed by replacing the highly correlated variables with a linear combination of them,  $Z = a *$

$vol + b * val$ . The coefficients of the linear combination are solutions of the imposed constraints system of inequalities:

$$\begin{cases} cov(BET, Z) < \min\{cov(BET, vol), cov(BET, val)\} \\ cov(trans, Z) > \max\{cov(trans, vol), cov(trans, val)\} \end{cases} \quad (9)$$

**Table 3:** Variance-Covariance matrix

	trans	BET	vol	val
trans	2904.25			
BET	-988.33	6041.15		
vol	22919.3	5621.93	671025	
val	20071	5509.73	599389	535908

The assumptions regarding the covariances are fulfilled:

$$\begin{aligned} cov(vol, val) &> 0 \\ cov(trans, vol) &> 0 \\ cov(trans, val) &> 0 \end{aligned}$$

Replacing the corresponding covariances in the sistem of inequations (9), it becomes:

$$\begin{cases} 5621.93a + 5509.73b < \min\{5621.93, 5509.73\} \\ 22919.3a + 20071b > \max\{22919.3, 20071\} \end{cases}$$
